		It is not anticipated to see dust levels outside study area on protected and notable areas differing from baseline conditions, much of the dust will be limited with the proposed mitigation measures. There are seasonal aspects that may affect the outcome of dust impacts including rain. Therefore, there are less potential impacts anticipated throughout June – October where there is generally more rain. Additionally, wind can impact the amount of dust that would be spread. The windy months in Cayman include October – March with a peak in December. The impacts of this potential effects are anticipated to be reversible at end of construction. The impacts of dust would have the potential to be seen at regular intervals through construction of the ISWMS infrastructure while active land preparation is occurring. The potential impacts from dust are reversible to baseline conditions after construction is completed. Vehicular traffic will decline, and grounds will be stabilized as applicable.								

Potential Effect	Mitigation Measures and Best Management Practices Proposed	Residual Environmental Effect Characterisation and Rationale						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Noise / light / visual disturbance including from movement of construction workers disturbing wetland/ migratory birds potentially on habitat linked to proposed Ramsar sites and protected and notable species around the ISWMS Site	During construction: – Limit construction activities to daylight hours – Ensure equipment meets industry standards with respect to noise level thresholds – Undertake regular maintenance of the equipment as part of the preventative maintenance plans implemented for all mobile and stationary equipment – Train Site personnel to ensure equipment is used in ways that minimize noise – Control noise by maintaining separation distance between source and receptor and equipment design, where feasible – Establish an exclusion barrier within the Site boundary to restrict fauna access to the Site; maintain throughout construction – Ensure engines are turned off when possible; vehicles will not be left to idle – Broadband reversing alarms will be chosen instead of tonal alarms	VL	SSA OSA	A	ST	R	R	Minimal offsite and onsite disturbance effects to fauna including noise, light, visual disturbances with the implementation of mitigation measures	Not significant as effects from noise and light disturbance are only anticipated during construction and mitigations in place to maintain equipment will eliminate the effects to species
		There is a very low impact anticipated to overall disturbance on wetland and migratory birds on Ramsar sites and on and around the Site. The Ramsar sites are approximately 2.8 miles (4.5 km) east and 4.7 miles (7.5 km) north away from the Site and therefore will not be disrupted by construction activities. Seasonal variations of this impact may impact the outcome of this effect including wind speed and cloud cover that may allow for light and sound to travel further. This is a short-term impact as the impacts are reversible at end of construction due to the reduction of construction activities causing potential effects. Effects would occur at regular intervals through construction as there is continued disturbance on Site. Therefore, the frequency is listed as regular. The impacts are reversible at end of construction as the construction causing the potential impacts would be eliminated. Although it is not anticipated for impacts to reach these areas with the implementation of mitigation measures. Thus, the residual effect is listed as partially reversible.								

Potential Effect	Mitigation Measures and Best Management Practices Proposed	Residual Environmental Effect Characterisation and Rationale						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Spills of oil, gasoline, and other fluids into natural communities around the ISWMS Site	During construction and operation: – All machinery should be inspected for fluid leaks or other potential pollutants. The Contractor/Operator should evaluate each piece of equipment to ensure all risk of spills or sediment release due to its use is mitigated prior to putting it into service – Proper machinery inspections and maintenance – Conduct equipment maintenance and refuelling at the designated and properly contained maintenance areas located well away from watercourses and wetlands and outside retained vegetation areas – Implement an emergency and response management plan to address the potential for spills	L	SSA	NA	ST		R	PR No residual effects from spills into natural communities around the ISWMS Site	Not significant as mitigations in place will ensure there is no impacts to natural communities around the Site from spills.
		There is a low magnitude of potential impact to the Site due to spills of oil, gasoline, and other fluids into natural communities on Site due to machinery on Site utilizing these materials to operate. The impact caused by fluid spills is the same during all times of year as there is refueling of construction and operation equipment occurring. Therefore, given a timing ranking of not applicable. Will return to baseline after construction as construction activities will be completed, and the amount of construction machinery would decrease, and regular activities would occur on Site, resulting in less opportunity for spills to occur. Therefore, resulting in a short-term duration. There is potential for spills is to occur at regular intervals throughout construction and operation, as refuelling of equipment and machinery is occurring. As such, given a frequency rating of regular. This effect is partially reversible as mitigation measured can return to environment to baseline conditions. All spills are to be addressed immediately with the emergency response management plan that is put into place before construction begins.								

Potential Effect	Mitigation Measures and Best Management Practices Proposed	Residual Environmental Effect Characterisation and Rationale						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Soil erosion and sedimentation into adjacent areas to the ISWMS Site	During construction: – Limit vegetation clearing only to areas where construction works are being completed to prevent sediment being exposed During construction and operation: – Establish and maintain erosion and sediment control fencing in good working order to capture any sediment migration whilst construction works are being completed – Maintain erosion and sediment control fencing in place until final Site development, or stabilize soils with permanent vegetation (e.g., annual seed mix and/or plantings) – Routinely inspect erosion and sediment control measures, including following storms, and repair as required All machinery should be inspected for fluid leaks or other potential pollutants. The Contractor should evaluate each piece of equipment to ensure all risk of spills or sediment release due to its use is mitigated prior to putting it in to service – Trucks and equipment shall be cleaned prior to leaving the Site to prevent mud/dirt from tracking onto roads	L	OSA	A	ST	R	PR	No offsite impacts from soil erosion or sedimentation into adjacent areas	Not significant as mitigations will ensure the stabilization of soils after construction and maintain sediment and erosion control fencing to limit movement of sediments.
		The magnitude of soil erosion and sedimentation into adjacent to the ISWMS Site outside of the study area is low due to the 33 acres (13.35 hectares (ha)) of terrestrial habitat and 1.7 acres (0.7 ha) of inland mangrove habitat that has been removed to accommodate this project which results in exposed soils on the ISWMS Site. Seasonal variation may impact the outcome of effect due to level of rain occurring during different seasons. June – October there is generally more rain that could cause increased risk of sedimentation into adjacent areas of the Site. The impacts from soil erosion and sedimentation will return to baseline after construction is completed as exposed soils will be stabilized and erosion and sediment control measures will be in place until establishment. As such the effect is listed as short-term. The effect has the ability to occur at regular frequency intervals throughout the construction phase due to exposed soils and movement of trucks and equipment. This effect is partially reversible as the mitigations can ensure a return to baseline conditions as the mitigation measures ensure any sediments cannot move to other areas that are adjacent to the Site.							

Potential Effect	Mitigation Measures and Best Management Practices Proposed	Residual Environmental Effect Characterisation and Rationale						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Deposition of contaminants on sensitive habitats or species within the range of emissions from the ISWMS Site	During operation: – Implementation of the Air Pollution Control (APC) System to capture emission contaminants. A system of humidification of the APC Residues will be provided for the flue gas residue discharge process. – Appropriate disposal of APC materials into designated engineered Residual Waste Landfill (RWL) – Regular inspection of facility and implementing good housekeeping action when required. – The Construction and Demolition processing operations will be undertaken in the open air and crushing and screening equipment will be fitted with water misters to reduce dust emissions. – Detail design shall consider including dedusting (suction to filter) in order to avoid dust emissions during the residues discharge from silo the truck.	VL	OSA	NA	LT	C	PR	No offsite impacts to sensitive habitats or species from deposition of contaminants during operation	Not significant as the APC system will capture the contaminants will be in place throughout operation.
		This effect would have a very low magnitude impact on sensitive habitats within the range of the ISWMS as the APC system implemented will capture the contaminants upon release. There are no seasonal variants that will impact the effect as the emissions will be released continuously throughout operation. The effect from emissions would occur during operation of the ISWMS Site. The duration is listed as long term as emissions will be released throughout operations of the ISWMS Site. Though, it is anticipated that mitigation measures are sufficient to negate potential effect throughout operations. The effect is listed as continuous frequency as the emissions will be released continuously throughout operation. The effect of deposition of contaminants on sensitive habitats is listed as partially reversible as the APC system will capture the contaminants upon release. Additional mitigation measures listed will also ensure limited impacts from this effect.							

Potential Effect	Mitigation Measures and Best Management Practices Proposed	Residual Environmental Effect Characterisation and Rationale						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Vehicle strikes on protected and notable species causing injury or death on the ISWMS Site	During operation: – All Site personnel should be trained in general protected species awareness and identification of protected species with the potential to occur on Site – Visual inspections will be completed daily before works commence. If fauna is found on Site during the work measures will be taken to allow fauna to leave the work area passively. Active relocation should be a last resort; if it is required, it will be completed in a manner that prevents harm to fauna – Should the animal be resident within the Site (remaining on-Site longer than 24 hours), injured, or eggs/nests are observed, additional measures to avoid impacts may be required before work can restart – All vehicles and equipment will follow the posted speed limit, to reduce the potential for wildlife collisions – Information posted in construction and operation offices of protected species and siting management plan – Have an ecologist or experienced environmental professional on Site to confirm species presence and identification	L	SSA	NA	LT	C	PR	No increase in mortality of protected species due to construction and operations works	Not significant as mitigations will ensure there is limited vehicle strikes on protected species.
		The impact on all terrestrial protected and notable species from vehicle strikes magnitude is low on Site. The ISWMS Site will be accessed along the same route as the current GTLF operations: from the South via Seymour Drive. Security has been addressed on the ISWMS Site by the proposed construction of a 12 foot (ft) (3.66 metre (m)) high metal chain link perimeter fence, which will also aid in keeping fauna outside of the ISWMS Site. Additionally, the fencing will be reinforced by species exclusion fencing. There is no seasonal variation of the effect. Impacts will be the same throughout all conditions on Site as species can pre present on Site throughout the year. The effect from vehicle strikes would occur during operation of the ISWMS Site. The duration is listed as long term as there is a potential for vehicle strikes to occur throughout the operation of the Site. It is anticipated that mitigation measures are sufficient to negate potential effect throughout operation. There is a continuous potential risk of the effect as there is continuous vehicular traffic on Site that has to potential to cause vehicular strikes on protected species. The effect from vehicle strikes is partially reversible as with mitigations utilized the risk of vehicle strikes is lowered and will return the effect to baseline conditions.							

Potential Effect	Mitigation Measures and Best Management Practices Proposed	Residual Environmental Effect Characterisation and Rationale						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Lighting from operation causing disturbance to protected and notable species around the ISWMS Site	During operation: – Limit operation activities to daylight hours – Reduce the intensity of lighting fixtures – Ensure downcast lighting on building where lights are required overnight	VL	OSA	NA	LT	C	PR	Minimal effects to fauna from lighting during operation	Not significant as the mitigation measures in place limit the light causing disturbance to species.
		The impact to terrestrial notable species outside of the Site from light is anticipated to be very low. Operations should be limited to during day light hours allowing for minimal light pollution to the Site during evening hours when impacts to species would occur from light. As 90 percent of the activity at the ISWMS Site occurs from dawn to dusk, lighting is restricted to the main access road (to allow for solid waste deliveries) and building eves. The impacts will not be seasonally variant as the lighting conditions will be the same throughout the year for security purposes. The effect of lighting would occur during operation of the ISWMS Site. The duration is listed as long term as lightening on the buildings will be consistent throughout operation for safety of the Site. It is anticipated that mitigation measures are sufficient to negate potential effects from lighting. With continued implementation of mitigation measures will ensure no impacts to species. There is a frequency of continuous listed for this effect, as throughout operation lighting will be used for safety of the Site. The impacts to species are partially reversible due to the fact that mitigation measures listed can return the impacts to baseline conditions.							

Potential Effect	Mitigation Measures and Best Management Practices Proposed	Residual Environmental Effect Characterisation and Rationale						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Noise from operation causing disturbance to protected and notable species around the ISWMS Site	During operation: – Ensure equipment meets industry standards with respect to noise level thresholds – Undertake regular maintenance of the equipment as part of the preventative maintenance plans implemented for all mobile and stationary equipment, to ensure all equipment is well-maintained to minimise noise emissions. – Train Site personnel to ensure equipment is used in ways that minimize noise – Control noise by maintaining separation distance between source and receptor and equipment design, where feasible – Establish an exclusion barrier within the Site boundary to restrict fauna access to the Site; maintain throughout operation – Ensure engines are turned off when possible; vehicles will not be left to idle – Legio-type blocks utilized for internal pushwalls providing additional noise absorption. – Construction and demolition process operations that have a high noise level (shredder and crusher) will only be activated intermittently which will reduce noise emission duration. – Bottom Ash process operations that have a high noise level (trommel) will only be activated intermittently which will minimise noise emissions duration. – High noise emitting equipment (baler and shear in particular) will only be used intermittently to minimise noise exposure time.	VL	SSA OSA	A	MT	R	R	Minimal offsite effects to fauna from noise during operation	Not significant as mitigations in place will reduce the noise impacts from operation on species.
		It is anticipated that the degree of noise effects on protected and notable species within and surrounding the Site are very low. Noise will mainly be confined within the ISWMS buildings. The project Site is located within a designated industrial area, therefore species in the area are used to movement and noise from industrial operations. There is a potential for a seasonal variation of noise impact due to wind speed and cloud cover that may allow for sound to spread more. The effect is seen to occur at regular intervals through operation due to the operation of machinery throughout working hours on Site. Effects causing disturbance from operations noise are reversible as the operations noise will be similar to baseline conditions based on adjacent landuses. Additional mitigation measures will be implemented to further reduce noise through noise absorption blocks incorporated into the facility design.								

5.1.2 Summary of effects

The predicted environment effects on the terrestrial environment are assessed to be adverse but not significant. Effects are associated with vegetation loss, fauna collision, soil erosion, dust, noise and vibration, invasive species, and spills. However, with the implementation of mitigation measures, best management practices that will be outlined in the Environmental Management Plan (EMP) in the Environmental Statement (ES), and any restoration or offsetting conditions from the Central Planning Authority or Development Control Board, the residual effect on the terrestrial environment is not significant. The effects anticipated are as summarized below:

– Minor vegetation removal and habitat provided by this vegetation
– Limited ability for introduction or spread of invasive species on Site
– No increase in mortality or injury of protected species due to construction and operations works.
– No offsite dust impacts on protected and notable habitats
– Minimal offsite noise, light and visual disturbance effects to fauna during construction and operation.
– No offsite impacts from soil erosion or sedimentation into adjacent areas
– No residual effects from spills into natural communities around the ISWMS Site
– No offsite impacts to sensitive habitats or species from deposition of contaminants during operation

While not significant, effects to the terrestrial environment will occur but will be mitigated through the implementation of the identified BMPs outlined in this ES. An EMP will be established to consolidate all mitigation measures and BMPs, which will be implemented prior to the start of the ISMWS construction.

5.1.3 Residual effects

The residual effects remaining after the implementation of mitigation measures during construction and operations identified for the terrestrial environment is minor vegetation removal and habitat provided by this vegetation.

6. Monitoring

For the purposes of construction works and operations, limited monitoring requirements have been identified. As previously noted in **Section 5**, the potential effects are adverse but not significant. The following monitoring requirements are recommended based on the residual effects identified:

During pre-construction:

– Fauna monitoring: exclusion fencing will be established around the ISWMS Site to mitigate fauna from entering areas where clearing or construction works are to be undertaken. Fencing is to be installed prior to construction works commencing. However, even with this fencing there is a potential for fauna to enter the Site. If fauna is found on Site measures will be taken to allow fauna to leave the work area passively. Active relocation should be a last resort; if it is required, it will be completed in a manner that avoids injury to the identified fauna.
– Erosion and sediment control monitoring: silt fencing will be established around the ISWMS Site to limit sediment run-off into the surrounding environment. Regular inspections (i.e., weekly, before and following 25 millimetres (mm) or more rainfall) should be conducted to identify any damage to the fencing and ensure a prompt repair.

During construction and operation:

– Fauna monitoring: If fauna is found on Site measures will be taken to allow fauna to leave the work area passively. Active relocation should be a last resort; if it is required, it will be completed in a manner that avoids injury to the identified fauna.
– Erosion and sediment control monitoring: Regular inspections (i.e., weekly, before and following 25 millimetres (mm) or more rainfall) should be conducted to identify any damage to the fencing and ensure a prompt repair.

Additional monitoring may be required based on approvals from the Central Planning Authority, Development Control Board, or if the vegetation clearing avoidance windows cannot be adhered to.

7. Conclusions

Grand Cayman is the most developed of the three islands, hosting 95 percent of the population. Wildlife have shown adaptation to artificial habitats resulting in complaints of wildlife inhabiting the developed environment. Protection of the natural environment is encouraged as this will maintain biodiversity within these landscapes (DaCosta-Cottam et al. 2009).

Natural heritage information from secondary sources and associated reports, and primary field data were collated to establish this document. There is potential for protected species occurrence in select areas throughout the Site, mainly of highly mobile, mangrove-dwelling wildlife species, such as birds and bats. As such, general habitat and species interaction mitigation measures have been provided as recommendations to be implemented throughout construction and operation phases.

Potential impacts associated with land development will be avoided or minimized through the implementation of recommended mitigation efforts outlined in this report. It is anticipated that the construction and operation of the proposed facility will result in limited residual effects to the terrestrial environment.

Hi Amy,

Please see the attached spatial data sharing agreement. Once you sign, we will release the data we have. Some of the questions below refer to matters which have already been settled as part of the ToR, so it is vital that this is followed.

Kind regards,

Hi Lauren,
Thanks back to you for also being so speedy!
Correct, we are following the final Terms of Reference dated October 4, 2021.

We are also looking to contact:
- National Trust for the Cayman Islands
- National Conservation Council
- Birdlife International
- Central Caribbean Marine Institute
- Shark Conservation Cayman

If you have any other recommendations, I would be grateful for the local input.

As for useful information, ideally were looking for any habitat mapping you may have, any designated areas within the study area, and if there are any protected species that we have missed off our list.

Thanks,

Amy Douglas

Hi Amy,

Thanks for getting back to me so quickly. I will ask our Senior GIS Officer (cc'd) to clip our habitat mapping extent to 2 km from the terrestrial study area site.

Could I please check that you are following the scope outlined in the final Terms of Reference? It outlined what kind of information was available and should be used for the assessment.

With respect to your final questions, could you clarify what kind of additional information would be useful?

Kind regards,

Lauren Dombowsky | Manager, Environmental Management Unit

Hi Lauren,

The terrestrial study area extends 2 km from the site boundary, apologies, I should have included that on the snips.

Our marine study area extends 12 nautical miles from site.

Subject: [EXTERNAL] Grand Cayman - Terrestrial Ecology Information Request

Hi Lauren,
Sharing the terrestrial ecology request this time. Please share with the appropriate team, thanks.

GHD Limited (GHD) was retained by DECCO Limited to determine the existing conditions of the terrestrial environment in the vicinity of the proposed Integrated Solid Waste Management System (ISWMS) site. The proposed site for the ISWMS is located to the north of central George Town towards the western coast of Grand Cayman, immediately south-west of the existing George Town Land Fill. The proposed ISWMS development consists of various new waste management facilities.

Please find mapping of the proposed site below.

West Bay
Rum Point
Old Man Bay
Grand Cayman
Breakers
George Town
Bodden Town

GHD's ecologists have completed background information reviews to characterize the associated terrestrial environment, with a focus on habitats, wildlife, protected species, and significant natural areas. Through the background review it was found that several species use the terrestrial habitats of the study area. A complete list of these species is attached.

We are seeking any additional natural environment assessments and protected species information for the listed location, and in particular any information about the mangroves east of the Esterly Tibbetts Highway.

Please let me know if you have any questions or require further information. We look forward to your response to our request.

Thank you,

Amy Douglas

Subject: Marine and Terrestrial Information for Grand Cayman
Attachments: Terrestrial Protected Species.pdf

Good afternoon,

GHD Limited (GHD) was retained by DECCO Limited to determine the existing conditions of the marine and terrestrial environment in the vicinity of the proposed Integrated Solid Waste Management System (ISWMS) site. The proposed site for the ISWMS is located to the north of central George Town towards the western coast of Grand Cayman, immediately south-west of the existing George Town Land Fill. The proposed ISWMS development consists of various new waste management facilities. We have contacted the Department of Environment and are also reaching out to The National Trust for the Cayman Islands to ensure our information is complete.

Please find mapping of the proposed site below.

GHD's ecologists have completed background information reviews to characterize the associated marine and terrestrial environments, with a focus on marine, coastal and terrestrial habitats, wildlife, protected species, and significant natural areas.

Marine Ecology

Through the background review it was found that the following are found within a 5-kilometre radius of the site:

- Marine Reserve Zones: George Town and Seven Mile Beach are approximately 1.5 km west of the Site. South Sound West and South Sound East are approximately 5 km south of the Site
- Line Fishing Zone: Jackson Point is approximately 4.5 km south of the Site
- Shore Line Fishing Zone: George Town approximately 1 km west of the Site
- No-Diving Overlay Zone: South Sound is approximately 5 km south of the Site
- Spawning Aggregation Overlay Zone: Southwest zone is approximately 5 km southwest of the Site off the shore of South Sound Beach.

As well, the following protected species were reported to use the seagrass bed and mangrove habitats of the Study Area (i.e., the Site including a 12 nautical mile buffer):

- All birds (mangroves)
- Bats (mangroves)
- Manatees (seagrass beds)
- Whales and dolphins (seagrass beds)
- Turtles (both)
- American and Cuban crocodile (mangroves)
- Sharks and rays (seagrass beds)
- All bony fish (both)

Terrestrial Ecology

Through the background review it was found that several species use the terrestrial habitats of the Study Area (i.e., the Site including a 2 kilometre buffer). A complete list of these species is attached.

We are seeking any additional natural environment assessments and protected species information for the listed location, and in particular any information about the mangroves east of the Esterly Tibbetts Highway. Please let us know if you have any questions or require further information. We look forward to your response to our request.

Thank you,

Good afternoon,
Please see the below request for information sent late last year.
We are hoping to receive a response to comprehensively complete our terrestrial assessment of the proposed site.

Thanks in advance for your help.
Kind regards,

Amy

Appendix 8.A

Hydrology and Hydrogeology Assessment

Executive summary

This Hydrology and Hydrogeology Assessment presents the baseline hydrological and hydrogeological conditions at the Site and an impact assessment to assess any relevant issues that may affect the proposed development, in accordance with the requirements of the Final Terms of Reference (ToR) written by Wood (2021).

The report indicates that the Site area is low-lying and affected by extreme weather events and is subsequently at risk of flood events.

Groundwater within the vicinity of the Site area is hydraulically connected to the ocean and other surface waters (such as the nearby mosquito control channels). This infers a tidal influence on the groundwater, and results in a considerable degree of mixing of saltwater and freshwater at the transition zone, which is anticipated to be present beneath the Site. As a result the groundwater is of high salinity and considered to be of 'low quality', and is therefore unsuitable for potable use without treatment. This is typical for groundwater on Grand Cayman, with the exception of some freshwater lenses located on the eastern side of the island.. Groundwater sampling within the Site area indicates that quality has been affected, presumed to be caused by emissions from the adjacent George Town Landfill (GTLF).

Surface water sampling at the Site and nearby mosquito control channels and North Sound also appear to be contaminated, presumably associated with GTLF emissions. Based on current trends, it is anticipated that concentrations of these contaminants may increase in the near future without influence from the proposed development at the Site.

Available information allowed for a qualitative impact assessment of the potential risks relating to hydrology and hydrogeology. Based on the current proposed design, a variety of potential environmental impacts associated with all relevant phases of the ISWMS have been identified. A number of these impacts have been assessed as Potentially Significant Impacts.

Appropriate mitigation measures for these Potentially Significant Impacts have been recommended, including a surface runoff management plan, a flood risk assessment (FRA), storm water management plan, and other strategies and measures to address the effects of water quality deterioration, groundwater yield reduction, and degradation of subsurface infrastructure.

Overall, due to the current unsustainable design and practices at the GTLF and resulting impacts to groundwater quality, it is likely that the construction of the ISWMS will result in net environmental benefits in the long-term. This is due to improved waste management practices and facilities replacing the current practices at the GTLF (unlined landfill) that are currently impacting groundwater and surface water quality.

A residual significant risk relates to potential flooding occurring at the site that exceeds the criteria adopted in the site design and impacts site infrastructure.

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

1. Introduction

1.1 Purpose of this report

GHD Limited (GHD) was retained by ReGen and the Cayman Islands Government (CIG) as approved by the Environmental Assessment Board (EAB) to undertake a hydrology and hydrogeology assessment as part of the Environmental Impact Assessment (EIA) for the proposed Integrated Solid Waste Management System (ISWMS, Project). This hydrology and hydrogeology assessment in part overlaps with matters considered in other assessments within the EIA. In particular, as highlighted within the ToR, Marine Ecology, Terrestrial Ecology, and Land Quality.

1.2 Overview of the Proposed Development

An Integrated Solid Waste Management System (ISWMS) is to be developed north of central Georgetown, Grand Cayman.

1.3 Study Areas

1.3.1 Spatial scope

The proposed Integrated Solid Waste Management System (ISWMS) is described in detail in Chapter 4 - Proposed Project & Overview.

The ISWMS will be located to the north of central George Town towards the western coast of Grand Cayman (the "Site"). The proposed boundary and layout of the ISWMS is shown in Figure 1.

The Study Area considered within this report encompasses the entire footprint of the ISWMS and some of its environs within the 2 km buffer zone, as outlined in the ToR (Wood, 2021). The ISWMS will include the following elements:

- Energy Recovery Facility (ERF)
- Non-Energy Recovery Facilities:
  - Site weighbridges
  - Green Waste Processing Facility (GWPF)
  - Construction and Demolition Waste Processing Facility (C&DWPF)
  - Bottom Ash Processing Facility (BAPF)
  - Abandoned and End of Life / Scrap Metal Processing Facility (ELV/SMPF)
  - Medical Waste Facility
  - Materials Recycling Facility
  - Household Waste Recycling Centre
  - Landfill Gas Facility (LGF)
  - Residual Waste Landfill (RWL)
- Ancillary Facilities:
  - Admin Building
  - Maintenance Building
  - CUC Substation

For the avoidance of doubt, this hydrology and hydrogeology assessment excludes:

- Potential contamination effects to, or from, soils, which are assessed separately elsewhere.
- Potential effects resulting from the subsequent closure of the existing landfills on each of the three islands including the Georgetown Landfill (GTLF).

As referenced in the ToR (Wood, 2021), the construction and operation of the proposed facilities on the Sister Islands will be managed by the DEH, and so will lie outside the scope of this EIA. Furthermore, with respect to the landfill closures on each of the three islands, it is understood that such activities will be subject to risk-based assessments that will be conducted outside the EIA.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

1.3.2 Temporal scope

The temporal scope considered within this report covers the construction, operation, and decommissioning of the ISWMS. GHD understands that the design life of the new facilities is 25 years.

DRAFT

GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

2. Methodology

2.1 Relationship with other Sections of the EIA

This Hydrology and Hydrogeology Assessment in part overlaps with matters considered in other assessments within the EIA. In particular, as highlighted within the ToR (Wood, 2021), Marine Ecology, Terrestrial Ecology, and Land Quality. The land quality chapter of the EIA is being prepared by GHD and due regard has been given to coordinate these chapters.

2.2 Potential receptors

The main potential water receptors and flood risk that could be affected by, or impact, the proposed development at the Site are summarised in Table 1, as identified in the ToR (Wood, 2021). It is important to note that this assessment examines potential changes of the Site on the water environment supporting designated conservation sites and potential undesignated groundwater-dependent terrestrial ecosystems (GWDTEs), not the habitats themselves, which are considered in the marine ecology and terrestrial ecology assessment reports.

Table 1 Potential hydrology (including flood risk) and hydrogeology receptors identified in the ToR (Table 5.13 in Wood, 2021).

Receptor	Location
Water Environment	
Ironshore Formation aquifer (limestone and marl bands up to 7.6 m thick)	Beneath the proposed development Site (0 to -25 ft / 0 to -7.6 m below mean sea level)
Bluff Group aquifer (Pedro Castle Formation aquifer, Cayman Formation and Brac Formation; dolomite, limestone and dolostone)	Beneath the proposed development Site (<-25 ft /-7.6 m below mean sea level)
North Sound (contains Replenishment and Environmental Zone which are marine protected areas)	2,460 ft (750 m) northeast of the Site
Water Use	
Groundwater abstraction for geothermal cooling system and potable water supply for use on the development site	At the proposed development Site
Groundwater abstraction for reverse osmosis plant for Laundry Facility	0.2 miles (0.3 km) northeast of the proposed development Site
Groundwater abstraction for potable water supply following desalination at WAC's Red Gate Road Water Works (reverse osmosis plants)	0.6 miles (1 km) southeast of the proposed development Site
Groundwater abstraction for geothermal cooling purposes at the CUC electrical power generation facility	0.5 miles (0.75 km) southeast of the proposed development Site
Groundwater abstraction for geothermal cooling purposes undertaken by various other developments including Fosters warehouses and the Owen Roberts International Airport, with expectation of further future projects	0.7 miles (1.2 km) southeast (Fosters warehouse) and south (Airport) of the proposed development Site
Humans, properties, and infrastructure within areas prone to flooding	
Site infrastructure, staff, and visitors	Proposed development Site
Surrounding land infrastructure, users, and visitors	Surrounding land

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

2.3 Assessment methodology

The assessment methodology is based on that prescribed within the ToR (Wood, 2021).

2.3.1 Consistent terminology

To assist the reader, consistent terminology has been adopted within this Hydrology and Hydrogeology Assessment. In particular, the word ‘effect’ is used to describe the consequence of environmental changes that are caused by development-related activities. The word ‘impact’ has not been used other than in the phrase EIA or where it appears in references).

2.3.2 Review of existing conditions

Available secondary sources of information were collected and reviewed to characterize the existing hydrological and hydrogeological conditions at the Site. A number of documents were identified within the ToR (Wood, 2021) and, in preparing this Hydrology and Hydrogeology Assessment, GHD identified additional relevant documents. All documents referred to have been cited within the text and fully referenced in Section 7.

It should be noted that where data (*e.g.*, contaminant analysis results) required extraction from the electronic documents (*e.g.,* PDF) provided, this has been done on a ‘best endeavours’ basis. If necessary, scanned images have been converted using optical character recognition (OCR) technology. However, GHD cannot guarantee the accuracy of the original third party data, nor in the fidelity of any OCR or transcription, whether manual or digital.

The following sources of secondary information have been considered in relation to hydrology and hydrogeology:

– Google Earth – web-based aerial imagery.
– Online topographic map (http://en-gb.topographic-map.com/places/George-Town-133291).
– Cayman Islands Government (CIG), 1992. Environmental Assessment of Grand Cayman Sanitary Landfill, Grand Cayman Island, B.W.I.
– Wood, 2021. Terms of Reference.
– GHD, 2023. GTLF Environmental Risk Assessment.
– GHD, 2023. Flood Risk Assessment.
– Carbex Geological Services Ltd, 2023. ReGen Geological Report.
– GHD, 2023. ISWMS Works Delivery Plan.
– GHD, 2023. ISWMS Service Delivery Plan.
– R.C. Minning & Associates, Inc (2023). Hydrogeological Investigation ReGen Geothermal System. Grand Cayman Island, Grand Cayman.
– Intergovernmental Oceanography Commission Website (http://www.ioc-sealevelmonitoring.org/station.php).

2.3.3 Site visits, inspections, and investigations

Due to the limited timescales, it was not possible for GHD to undertake bespoke Site visits or surveys, nor undertake any additional Site investigations or monitoring during the preparation of this Hydrology and Hydrogeology Assessment. Consequently, the following assessments are based entirely on secondary sources, including pre-existing environmental investigation and assessment reports relating to the Site.

However, GHD is aware that groundwater sampling works have recently been undertaken in some areas at the Site by DEH. The results of this have been incorporated into this assessment where possible.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

2.3.4 Hydrology (surface water) and hydrogeological (groundwater) assessment

Based on the information reviewed, the assessment of potential hydrological and hydrogeological effects involved:

– Describing baseline hydrological and hydrogeological conditions:
  - Outlining the local surface water and groundwater information (relating to quality and levels).
  - Identifying factors that may affect the future baseline.
– Assessing hydrological and hydrogeological risks to identify potentially significant effects:
  - Details of the method used to assess each risk (presented in Section 2.3.4.1).
  - Details of the method adopted to assess the significance of each effect (presented in Section 3.3.5).
– Consideration of the influence of any cumulative effects of different hydrological and hydrogeological issues.
– Presenting relevant mitigation measures for any significant effects following accepted engineering practice standards with clear confirmation that the proposed mitigative solutions are technically and environmentally sound.

2.3.4.1 Hydrological and hydrogeological risk assessment

As requested in the ToR (Wood, 2021), the assessment of hydrology and hydrogeology has been conducted, where possible, in line with the Directive for EIAs (2016) issued in accordance with The National Conservation Law (2013) and will take into account the Water Authority Act (2018 Revision). Section 19 of which states that groundwater vests in the name of the Crown and appoints the Water Authority Cayman (WAC) as the custodian of groundwater in the name of, and on behalf of, the Crown.

As there are no specific standards for water quality within the Cayman Islands, the assessment adopted Florida Clean up Standard target levels (CCTLs) where available. Given the brackish groundwater within the assessment area, and proximity to marine surface water features, target levels protective of both low yield/poor quality groundwater and marine surface water are considered appropriate for use at the Site. The CCTLs for such ground waters are generally higher (*i.e.* 10-times) than those for more sensitive groundwaters. According to Chapter 62-780 of the Florida Administrative Code (F.A.C) (State of Florida, 2005), 'Poor quality' means "*groundwater within the affected monitoring zone with background concentrations, as defined in subsection 62-780.200(3), F.A.C., that exceed any of Florida's Primary or Secondary Drinking Water Standards referenced in Chapter 62-550, F.A.C.*" and 'Low yield' means "*groundwater that is contained in an aquifer that has an average hydraulic conductivity of less than one foot per day, determined by performing slug tests or an equivalent method for determining hydraulic conductivity on a minimum of three monitoring wells in each affected monitoring zone; and a maximum yield of 80 gallons per day, determined by pumping a four-inch well screened across the cross-section of the plume, for a minimum of two hours*". The ToR (Wood, 2021) states that an aquifer with hydraulic connectivity between the centre of the landfill into the North Sound has an average of 12 feet per day. However, given the brackish nature of the groundwater beneath the Site and lack of any nearby abstractions, the use of these criteria at the Site is considered to be reasonable. Where relevant CCTLs are not available, alternative criteria have been sought from alternative sources, such as USEPA, European Water Framework Directive (WFD), and World Health Organisation (WHO).

2.3.5 Future Baseline

The future baseline considers the changes that would take place in the absence of the advancement of the ISWMS project, including natural occurrences and process that would alter the current baseline conditions during the anticipated lifetime of the project, or other changes occurring in the surrounding area which may positively or negatively effect environmental conditions.

In the event of unavoidable changes being identified in relation to hydrology and hydrogeology, these are reflected in suitable amendments to the current baselines in the relevant section of this report.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

2.3.6 Significance evaluation

2.3.6.1 Value and Magnitude of Receptors

The significance of the effects resulting from the ISWMS project has primarily been determined by the value of the relevant hydrological features and the magnitude of change as a consequence of the ISWMS project. In terms of the hydrology and hydrogeology, the key types of effects relate to water levels, flow, and quality. Where appropriate, effects on surface water flows, effects on immediate and downstream morphology, sediment dynamics, and flood risk have also been considered.

Described below is the method and criteria which have been used to determine value, magnitude of change, and the significance of the effects.

The value of hydrological and hydrogeological water features scoped into the assessment has been associated with the importance of the surface water or groundwater features. Table 2 provides a summary of the criteria used in the valuation of water features and introduces the concept of receptor type (a collection of receptors whose value is assessed using the same set of criteria). Professional judgement has been applied to the assessment due to the semi-quantitative nature of the criteria.

The magnitude of change on water receptors considered independently from the value of the receptor. Its assessment - both potential, taking into account any inherent integral mitigation to the proposed ISWMS, alongside residual, following the implementation of additional mitigation measures – is also semi-quantitative and therefore professional judgement has also been applied to the assessment. Table 2 provides examples of how various levels of change can be determined with respect to water features.

Table 2 Summary of value definition of hydrology (including flood risk) and hydrogeology receptors. [Source: Wood, 2021]

Value	Criteria	Receptor type*	Examples
High	Features with a high yield, quality or rarity with little potential for substitution	Aquatic environment	Conditions supporting a site with an international conservation designation, where the designation is based specifically on aquatic features. High status (quantity and/or quality) watercourse, also any associated upstream unclassified watercourse. Principal aquifer (high permeability, able to support water supply and/or watercourse baseflow on a strategic scale).
	Water use supporting human health and economic activity at a regional scale	Water use	Regionally important public surface water or groundwater supply (and associated catchment) or permitted discharge.
	Features with a high vulnerability to flooding	Flood risk	Land use type considered as 'Essential Infrastructure' (i.e., critical national infrastructure, such as essential transport and utility infrastructure) and 'Highly Vulnerable' (e.g. police/ambulance stations that are required to operate during flooding, mobile homes intended for permanent residential use).
Medium	Features with a medium yield, quality or rarity, with a limited potential for substitution	Aquatic environment	Conditions supporting a site with a national conservation designation, where the designation is based specifically on aquatic features. Good status (quantity and/or quality) watercourse, also any associated upstream unclassified watercourse. Secondary aquifer (permeable, able to support water supply and/or watercourse baseflow on a local scale).

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Value	Criteria	Receptor type*	Examples
	Water use supporting human health and economic activity at a local scale	Water use	Local public surface water and groundwater supply (and associated catchment) or permitted discharge. Licensed non-public surface water and groundwater supply abstraction (and associated groundwater catchment) which is relatively large relative to available resource, or where raw water quality is a critical issue, e.g., industrial process water, or permitted discharge.
	Features with a medium vulnerability to flooding	Flood risk	Land use type considered as 'More Vulnerable' (e.g., most types of residential development, hostels and hotels, landfill and waste management facilities).
Low	Features with a low yield, quality or rarity, with some potential for substitution	Aquatic environment	Conditions supporting a site with a local conservation designation, where the designation is based specifically on aquatic features, or an undesignated but highly/moderately water-dependent ecosystem. Lower status (quantity and/or quality) watercourse, also any associated upstream unclassified watercourse. Secondary aquifer (lower permeability, limited yield).
	Water use supporting human health and economic activity at household/individual business scale	Water use	Licensed non-public surface water and groundwater supply abstraction (and associated catchment), which is small relative to available resource, or where raw water quality is not critical, e.g., cooling water, spray irrigation, mineral washing or permitted discharge. Unlicensed potable surface water and groundwater abstraction (and associated catchment) e.g., private domestic water supply, well, spring or permitted discharge.
	Features with a low vulnerability to flooding	Flood risk	Land use type considered as 'Less Vulnerable' (e.g., most types of business premises).
Very Low	Commonplace features with very low yield or quality with good potential for substitution	Aquatic environment	Conditions supporting an undesignated and low water-dependent ecosystem. Unclassified watercourse. Non-aquifer (low permeability, minimal yield)
	Water use does not support human health, and of only limited economic benefit	Water use	Unlicensed non-potable surface water and groundwater abstraction (and associated catchment) e.g., livestock supply.
	Features that are resilient to flooding	Flood risk	Land use type considered as 'Water-compatible use' (e.g., appropriately designed flood control infrastructure; water transmission infrastructure).

Notes:

* Receptor types map onto receptors such as those identified in Table 2 as follows:

- Aquatic environment – aquifers, watercourses, conditions supporting GWDTEs and designated conservation sites
- Water use – springs, abstractions
- Flood risk – humans, properties and infrastructure.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 3 Summary of hydrology (including flood risk) and hydrogeology magnitude of change definition [Source: Wood, 2021

Magnitude	Criteria	Receptor type	Example
High	Results in major change to feature, of sufficient magnitude to affect its use/integrity.	Aquatic environment	Deterioration in river flow regime, morphology or water quality, leading to sustained, permanent or long-term breach of relevant conservation objectives (COs) or non-temporary downgrading (deterioration) of watercourse status (quantity and/or quality) or dependent receptors. Deterioration in groundwater levels, flows or water quality, leading to non-temporary downgrading of status (quantity and/or quality) of aquifer or dependent receptors.
		Water use	Complete or severely reduced water availability and/or quality, compromising the ability of water users to abstract.
		Flood risk	Change in flood risk resulting in potential loss of life or major damage to property or infrastructure.
Medium	Results in noticeable change to feature, of sufficient magnitude to affect its use/integrity in some circumstances.	Aquatic environment	Deterioration in river flow regime, morphology or water quality, leading to periodic, short-term and reversible breaches of relevant COs, or potential temporary downgrading of watercourse status (quantity and/or quality) or dependent receptors. Deterioration in groundwater levels, flows or water quality, leading to potential temporary downgrading of status (quantity and/or quality) of aquifer or dependent receptors.
		Water use	Moderate reduction in water availability and/or quality, which may compromise the ability of the water user to abstract on a temporary basis or for limited periods, with no longer-term effect on the purpose for which the water is used.
		Flood risk	Change in flood risk resulting in potential for moderate damage to property or infrastructure.
Low	Results in minor change to feature, with insufficient magnitude to affect its use/integrity in most circumstances.	Aquatic environment	Slight change in river flow regime, morphology or water quality, but remaining generally within COs, and with no short-term or permanent change to watercourse status (quantity and/or quality) or dependent receptors. Slight deterioration in groundwater levels, flows or water quality, but with no short-term or permanent downgrading of status (quantity and/or quality) of aquifer or dependent receptors.
		Water use	Minor reduction in water availability and/or quality, but unlikely to affect the ability of a water user to abstract.
		Flood risk	Change in flood risk resulting in potential for minor damage to property or infrastructure.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Magnitude	Criteria	Receptor type	Example
Very Low	Results in little change to feature, with insufficient magnitude to affect its use/integrity	Aquatic environment	Very slight change in river flow regime or water quality, and no consequences in terms of COs or watercourse status (quantity and/or quality) or dependent receptors. Very slight change in groundwater levels or quality, and no consequences in terms of status (quantity and/or quality) of aquifer or dependent receptors.
		Water use	Very slight change in water availability or quality and no change in ability of the water user to exercise licensed rights or continue with small private abstraction.
		Flood risk	Increased frequency of flood flows, but which does not pose an increased risk to property or infrastructure.

2.3.6.2 Significance of Effects

As outlined in the ToR (Wood, 2021) both the value of the water feature and the magnitude of change are used to derive the overall significance of the water-based effects. In the case of this assessment, the effects are assessed as being significant, probably significant or not significant as per the matrix in Table 4, with 'Major' effects taken to be 'Significant' and 'Moderate' effects, in the majority of cases, the significance can be determined as 'Beneficial', 'Adverse' or 'Neutral'.

Table 4 Significance evaluation matrix relating to the water environment. [Source: Wood, 2021]

		Magnitude of change			
		High	**Medium**	**Low**	**Very Low**
Value	**High**	Major (Significant)	Major (Significant)	Moderate (Probably significant)	Minor (Not significant)
	Medium	Major (Significant)	Moderate (Probably significant)	Minor (Not significant)	Negligible (Not significant)
	Low	Moderate (Probably significant)	Minor (Not significant)	Negligible (Not significant)	Negligible (Not significant)
	Very Low	Minor (Not significant)	Negligible (Not significant)	Negligible (Not significant)	Negligible (Not significant)

Note: 'Significant' effects are those identified as 'Major'. 'Moderate' effects would normally be deemed to be 'significant'. However, there may be some exceptions, depending on the environmental topic and the application of professional judgment.

Residual effects remaining as 'Significant' following the implementation of additional mitigation measures will be identified. It is possible that there are no additional mitigation measures required, or that there are no residual effects following the application of mitigation measures.

2.4 Cumulative effects

The ToR (Wood, 2021) identified two potential future developments in the vicinity; the Planned Area Development for Camana Bay; and the proposed Cruise Berthing Facility.

Due to the limited radius of influence of the hydrology and hydrogeology effects, cumulative effects in relation to these, or any other future developments, are unlikely. If cumulative effects are identified during the hydrological and hydrogeological assessments, their significance will be assessed in the relevant section of this report.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

2.5 Consultation

Consultation with Water Authority Cayman (WAC) has occurred throughout the EIA process.

3. Current baseline: hydrology and hydrogeology

3.1 Topography

According to the ToR (Wood, 2021):

– Site elevation ranges approximately between 7 and 20 ft (2.13 to 6.10 m) above mean sea level.
– The surrounding land is mainly flat and low lying and, where developed, is formed of reclaimed former mangrove swamp.

3.2 Climate

The following meteorological conditions for Grand Cayman are summarised in The climate for Cayman Islands is tropical marine, including warm, rainy summers from May to October, with average temperatures approximately 80 to 85°F (27 to 29°C). The maximum average monthly temperature in July at 83.9°F (28.8°C), and winters are only slightly cooler on average, from November to April, with the lowest average monthly temperatures in February at 77.2°F (25.1°C). The heaviest rainfall typically occurs in October. Tropical low-pressure systems affect Grand Cayman during the summer months, and can comprise tropical waves, depressions, tropical storms, and hurricanes (with sustained winds at times exceeding speeds of 74 mph (119 kmph)). Hurricanes that periodically affect the island typically range from Category I through Category V on the Saffir Simpson scale. The hurricane season for this region is June 1 to November 30. Throughout the winter period, the Cayman Islands can experience ‘Nor’wester‘ storms which can result in cooler temperatures and strong northwest winds across the islands.

Table 5 (Cardno ENTRIX, 2013), as outlined in the ToR (Wood, 2021).

Average monthly rainfall in Grand Cayman varies from just under 1 inch (25 mm) per month, to over 20 inches (508 mm) per month. Average annual rainfall varies significantly, depending on individual storm events. The long-term annual average rainfall is 64.3 inches (1.63 m).

The climate for Cayman Islands is tropical marine, including warm, rainy summers from May to October, with average temperatures approximately 80 to 85°F (27 to 29°C). The maximum average monthly temperature in July at 83.9°F (28.8°C), and winters are only slightly cooler on average, from November to April, with the lowest average monthly temperatures in February at 77.2°F (25.1°C). The heaviest rainfall typically occurs in October. 3.3 Geology

The geology in the vicinity of the proposed development is described in CIG (1992), WAC (2001), Jones (1994), and Carbex Geological Services Ltd (2023) (Appendix 3) and summarised in Table 6, sourced from the ToR (Wood, 2021).

The Cayman Islands are outcrops of an undersea mountain range, known as the Cayman Ridge, within a tectonically active region. Elevated above the general level of the Cayman Ridge, the islands are formed from a separate fault block. The islands have a granodiorite base, capped with basalt and approximately 1,300 m of Tertiary carbonates – limestones and dolostones. The Tertiary Period geological succession consists of the Pleistocene Ironshore Formation unconformably overlying the Bluff Group. At surface level across much of Grand Cayman is peat (formed within the low-lying wetlands), alongside some areas of imported fill.

The Ironshore Formation comprises coralline limestones (from soft to hard) with hard lenses interspersed throughout, alongside coral ledge and pockets of calcareous sand. The underlying Bluff Group comprises the following formations; Pedro Castle Formation, Cayman Formation, and Brac Formation. The Cayman Formation exhibits a number of geological features including joints, fractures, and (primarily in-filled) sinkholes and solution cavities. The Cayman Formation is divided into the upper 'cap rock' (5.5 to 65 ft (1.7 to 19.8 m) below ground level (bgl)), and the lower part of the Cayman Formation which extends to depths below 250 ft (76 m) deep. 'cap rock' (5.5 to 65 ft (1.7 to 19.8 m) below ground level (bgl)) and the lower part of the Cayman Formation that extends to depths below 250 ft (76 m) deep. The 'cap rock' is formed of hard dolostones that have low porosities and low permeabilities, and the lower unit of the Cayman Formation is formed of relatively friable dolostones with high porosities and high permeabilities.

Investigation of the geology of the Site area by Carbex Geological Services Ltd (2023) confirms that the geological makeup noted above is consistent with the geology beneath the Site. Data based upon three wells installed at the Site in December 2022, concludes that the Site is underlain by the following strata, from youngest to oldest; Ironshore Formation, Pedro Castle Formation, Cayman Formation, and Brac Formation. The characteristics of which correspond to those identified in other wells within the vicinity of the Site. Porosity and permeability values were obtained for twenty-five samples from various parts of the succession in each well on site, with all formations ranging from 10.1 to 39.7%.

Table 6 Geology summary for the Cayman Islands. [Source: Wood, 2021]

Period	Series	Formation	Elevation (ft/m above mean sea level)	Thickness (ft / m)
Made ground	Made ground	Imported fill	+1.5 to +4.0 ft +0.45 to +1.2 m	2.5 ft/ 0.75 m
Quaternary	Holocene	Peat (swamp deposits)	0 to +1.5 ft 0 to +0.45 m	1.5 ft/ 0.45 m (4-10 ft/ 1.2-3.0 m below wastewater treatment lagoons to the west of the proposed development)
Quaternary	Pleistocene	Ironshore Formation (calcareous marl)	0 to -3.0 ft 0 to -0.9 m	3.0 ft/ 0.9 m
Quaternary	Pleistocene	Ironshore Formation (very soft friable limestone)	-3.0 to -7.5 ft -0.9 to -2.3 m	4.5 ft/ 1.4 m
Quaternary	Pleistocene	Ironshore Formation (soft friable limestone and marl bands)	-7.5 to -25 ft -2.3 to -7.6 m	17.5ft/ 5.3 m
Tertiary	Pliocene	Bluff Group- Pedro Castle Formation (hard dolomite and limestone)	-25 to -45 ft -7.6 to -13.7 m	20ft/ 6.1 m
Tertiary	Miocene	Bluff Group- Cayman Formation (dolostone)	-45 to >-300 ft -13.7 to >-91.4 m	>250ft/ >76 m
Tertiary	Oligocene	Bluff Group- Brac Formation (limestone and sucrosic dolostone)	>-300 ft >-91.4 m	-

Notes: Based on information reported in CIG (1992), WAC (2001) and Jones (1992). Thickness of Brac Formation not reported.

3.4 Potential sources of ground and surface water contamination

Potential soil contamination at the Site, which may represent sources of groundwater and surface water contamination, is discussed in detail within the Land Quality Assessment of this EIA. This includes information regarding:

– The adjacent Georgetown Landfill (GTLF) including:
  - Its boundary and layout.
  - Its historical development.
  - Results of leachate sampling.
  - Plans for its closure, remediation, and restoration.
– Other known or potential sources of contamination within the proposed ISWMS footprint including:
  - The old scrap and tyre stockpile area (OSTSA).
  - The arsenic containment cell.
  - The equipment storage area (including the oil, hazardous waste storage area, and area of suspected bund overtopping in 2004).
  - Evidence of earlier waste disposal activities outside of the GTLF.

Based on the available information, groundwater and surface water contamination within the proposed ISWMS footprint is most likely to result from current and historical waste disposal activities at the GTLF, which is understood to

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

be owned by CIG. Management of the known environmental impacts of the GTLF is one of the drivers of the development of the ISWMS.

Overall, due to the current design and practices at the GTLF and potential resulting impacts to groundwater and surface water quality, it is likely that the construction of the ISWMS and its practices will result in net environmental benefits in the long-term.

3.5 Hydrogeology

The groundwater beneath the Site is reportedly tidally influenced, with a hydraulic gradient towards the North Sound to the east (CIG, 1992). Observation boreholes (OBHs) located around the GTLF have been used for groundwater level monitoring and assessment in relation to tidal cycles. An OBH within the central part of the landfill exhibited a head difference of between 0.45 ft (0.14 m) and 0.68 ft (0.2 m) (mean 0.56 ft (0.17 m)) above the corresponding tidal level within North Sound, with the groundwater levels indicating a tidal lag. The amplitude of the tidal fluctuations in North Sound were 1.2 times that of the OBH. Assuming a net mean hydraulic head of 0.56 ft (0.17 m), and an average distance from a central point in the landfill to North South of 3000 feet (914 m) and using an aquifer permeability of 0.00188 ft (0.00057 m) per minute (constant head permeability test measurement), alongside a porosity of 15%, the groundwater flow has been calculated at a rate of 12 ft (3.6 m) per day.

According to the ToR, assuming a net mean hydraulic head of 0.56 ft (0.17 m), and an average distance from a central point in the landfill to North South of 3,000 feet (914 m) and using an aquifer permeability of 0.00188 feet (0.00057 m) per minute (constant head permeability test measurement), alongside a porosity of 15%, the groundwater flow was calculated at a rate of 12 ft (3.6 m) per day[1].

More recent groundwater monitoring undertaken by Amec Foster Wheeler (2016) at 10 boreholes within and around the GTLF, on the western edge of the Site, is indicative of groundwater levels ranging from 1.87 ft (0.57 m) and 11.4 ft (3.47 m) bgl and subject to tidal variation (0.59 to 0.62 ft (0.18 to 0.19 m) across a 24 hour timeframe.

The tidal influence of the groundwater indicates hydraulic connectivity between the groundwater and ocean (Figure 2). This reportedly results in considerable mixing of saltwater from the ocean and freshwater, causing a transition zone of brackish water (Amec Foster Wheeler, 2016). This mixing zone was anticipated to be present beneath the Site. Although Amec Foster Wheeler did not determine groundwater flow direction, they did confirm that groundwater is considered to be in continuity with surface waters. GHD (2021) suggested that "*It can be assumed that the groundwater at the Site is flowing towards the canals and North Sound due to their closer proximity and proven tidal influence*".

Interpretation of the hydrogeological conditions on-Site, by R.C. Minning & Associates Inc (2023), details that the groundwater flow system directly in contact with both the North Sound and the Caribbean Sea with the water table elevation fluctuating (with a slight lag) in response to local tidal cycles.

The groundwater is also assumed to be in hydraulic connectivity with the various mosquito-control canals, including the 'northern channel' on the northern boundary of the Site (Section 3.6).

3.5.1 Available monitoring data

Quantitative water quality analysis data (surface water and groundwater) for the period of 2006 to December 2022 was provided by DART on 19 April 2023. GHD has relied upon this data and assumed that it is accurate and representative of the conditions at the Site during this period.

DART provided data as a spreadsheet of collated data for 2006 to June/July 2022 and as laboratory certificates and digital data for the 2022 analysis.

GHD has relied on the data within the spreadsheet and manually added the December 2022 data to it. However, in undertaking our assessment we note that:

– Some of the sampling locations within the spreadsheet do not correspond with sampling locations provided on the plan that GHD was issued, including: MW1, SW1, SW7, SWA1, SWA2, SWA4, SWA6, Drain.
– Some of the sampling locations have limited data points and variable sampling periods between locations, resulting in challenges in identifying data trends and allowing comparison between sampling locations.
– There are inconsistencies in the values presented in the spreadsheet compared to the equivalent values in the certificates of analysis. In undertaking this assessment, GHD has relied on the values within the spreadsheet.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

– The spreadsheet contained a substantial number of “numbers stored as text” and other discrepancies (e.g. spaces and other non-visible data). GHD has resolved these in order to allow the data to be queried and statistical analysis applied.
– In assessing the data GHD has assumed that any concentrations reported as being below the relevant Limit of Detection (LoD) has been assumed to be at that LoD. This is a highly precautionary assumption.
– For several samples and substances the LoD exceeded the respective CCTL, resulting in the data being inconclusive as to whether or not they exceed the CCTLs. As a highly precautionary assumption, these data points have been assumed to exceed the CCTLs.
– As discussed below, for several contaminants, apparent exceedances of the CCTLs were noted. However, examination of the data appears to indicate that many of these are due to 1000-fold discrepancies between concentrations and LoDs between different monitoring rounds. This is potentially indicative of the data either being subjected to laboratory dilutions, or variations in reporting units (e.g. µg/kg and mg/kg), rather than true exceedances.

3.5.2 Groundwater quality

Groundwater quality to the north of the Site, in and around the GTLF, has been monitored by DEH between 2006 and December 2022. The monitoring locations are shown in Figure 3 and the full dataset is provided in Appendix A. Groundwater samples were analysed for a wide suite of contaminants and the concentrations compared to applicable assessment criteria, predominantly CCTLs. A summary of these results is provided in Table 7.

In general, elevated concentrations of organic contaminants were not reported:

– Polychlorinated Biphenyls (PCBs) were not detected above the relevant LoD in any of the 41 samples tested.
– The concentrations of Volatile Organic Compounds (VOCs) were below relevant LoDs. However, Benzene, Toluene, Ethylbenzene, and Xylenes (BTEX), acetone, carbon disulfide, chlorobenzene, 1,4-dichlorobenzene, and cis-1,2-dichloroethene were detected in one or more samples but not at concentrations above the CCTL.
– Diesel Range Organics (DRO C10-C28) were detected in all 20 samples tested but Gasoline Range Organics (GRO C6-C10) were only detected in 5% of these samples. No assessment criteria are available for these contaminants.

Table 7 Summary of groundwater contamination within the Site between 2006 and December 2022. [Source: Appendix A]

Substance	Unit	Florida Clean Up Standard Target Levels (CCTLs)	Samples With Data (No.)	Samples Below LoD (%)	Samples Exceeding CCTLs (%)	Concentration		
						Minimum	Maximum	Mean

Alpha-BHC	µg/L	0.06	29	100	21	0.00098	0.95	0.9
Beta-BHC	µg/L	0.02	29	100	10	0.0012	0.95	0.10
Dieldrin	µg/L	0.02	29	100	38	0.0012	0.95	0.09

Notes: * This term is used in the data relied on by GHD, but these are different determinands so the meaning of this data is not clear. For the purpose of this assessment GHD has assumed that these values can be compared to the CCTL for ammonia.

Cells shaded red indicate an exceedance of the CCTL, cells shaded orange indicate exceedances where the LoD exceeds the CCTL, cells shaded green indicate that concentrations fall below the CCTL.

Consistent CCTL exceedances of ammonia or total nitrogen have been recorded in the north of the Site, alongside several isolated exceedances across the rest of the Site, but there does not appear to be any increasing or decreasing trend in concentrations over time. This may relate to the bund overtopping from the GTLF.

Exceedances of CCTL for Total Dissolved Solids (TDS) were identified across the majority of the Site, except for areas in the far south-east. These exceedances of TDS have been recorded since the earliest monitoring round in 2006 and appear to be significantly fluctuating over time with no obvious trend aside from generally exceeding the CCTL consistently. These fluctuations may potentially be explained by the location of the Site within the transition zone where considerable mixing of groundwater and saltwater occurs, together with any dissolved solids that either water body is transporting.

Exceedances of CCTL for both arsenic and antimony have been recorded in MW19 (south-east of the Site) and MW20 (south-west of the Site) in recent monitoring rounds, potentially indicating a potential relationship in their source and pathway into the groundwater. This may either be associated with the arsenic containment cell detailed within the Land Quality Assessment of the EIA, which is located in the centre/south of the Site, or the data may have been reported in the incorrect unit. The latter explanation may justify the high variability, inconsistency, and lack of apparent trend in these concentrations.

Historically, iron concentrations have been identified above the CCTL in MW1 (east, on Seymour Road, exact location not known), MW5 (Site centre, exact location not known), and MW8 (north-eastern corner). However, no data has been obtained from these locations since 2015, and therefore it is not possible to assess this trend over time or current status. In the more recent monitoring rounds, substantial exceedances of iron have also been found in MW19 (south-east of the Site) and MW20 (south-west of the Site). It is possible that these increases in iron concentrations may be related to the increases in arsenic and antimony that were identified within the same time frame and potentially sharing the same source, or the data may have also been reported in an incorrect unit.

Metals barium, beryllium, cadmium, chromium, copper, lead, nickel, selenium, thallium, and mercury also exceed their respective CCTLs and also exhibit highly fluctuating results with no trend. While this is potentially indicative of the groundwater being impacted by a wide range of metals, potentially associated with the GTLF, the results may also be caused by data discrepancies between monitoring rounds.

VOCs 1,2-dibromoethane, dibromomethane, and 1,2,3-trichloropropane also exceeded their respected CCTLs in all 55 samples; however, all 55 samples were also recorded below the LoD. As a result, the analysis of the data remains inconclusive.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Several CCTL exceedances of pesticides aldrin, alpha-BHC, beta-BHC, and dieldrin were also noted in several samples. As all sample data falls below the LoD, analysis of the exceeding data also remains inconclusive.

While no assessment criteria is available for DROs, concentrations have been identified above the LoD in MW-15A and MW16 within the area of suspected overtopping of the bund within the equipment storage area in 2004 in the south of the Site. Out of the three results obtained for this area (MW-15A in 2015 and 2016, MW16 in 2013) the maximum detected concentration is 1.7 mg/L in MW16 in 2013. It is possible that this concentration is related to the overtopped bund incident, however, as no earlier or more recent data has been obtained it is not possible to comment on any potential trends. It should also be noted that the concentrations within this area are consistent with other concentrations detected across the rest of the Site. The highest concentration recorded on Site is 26 mg/L in MW21 in 2016, on the northern boundary of the Site.

DRAFT

3.5.3 Groundwater abstractions

The ToR identified three groundwater abstractions within 2 km of the proposed development site as presented in Table 8. It is noted that the nearest abstraction is 0.5 miles (0.75 km) northeast of the proposed development Site.

Table 8 Potential groundwater abstraction receptors identified in the ToR

Receptor	Location
Groundwater abstraction for reverse osmosis plant for Laundry Facility	0.2 miles (0.3 km) northeast of the proposed development Site
Groundwater abstraction for potable water supply following desalination at WAC's Red Gate Road Water Works (reverse osmosis plants)	0.6 miles (1 km) east of the proposed development Site
Groundwater abstraction for geothermal cooling purposes at the CUC electrical power generation facility	0.5 miles (0.75 km) northeast of the proposed development Site
Groundwater abstraction for geothermal cooling purposes undertaken by various other developments including Fosters warehouses and the Owen Roberts International Airport, with expectation of further future projects	0.7 miles (1.2 km) northwest (Fosters warehouse) and south (Airport) of the proposed development Site

Due to the general high salinity of groundwater and lack of significant freshwater resources on Grand Cayman, potable water is reportedly supplied from desalinisation plants by reverse osmosis. Water is reportedly sourced from wells drilled deep into the limestone bedrock beneath the Island and is treated to drinking water quality standard (Wood, 2021, Cayman Water 2023). This abstraction occurs from wells with response zones exceeding 100 ft (30 m) deep (GHD, 2021). Abstractions for the WAC's Red Gate Road Water Works are reportedly sourced from a depth of approximately 100 feet (R. C. Minning & Associates, Inc 2023).

Although freshwater lenses are present in several isolated areas of Grand Cayman (Wood, 2021), these are not used as a primary source of drinking water for the Island. The Site is not considered to be in close proximity to any major freshwater lenses, with the nearest freshwater lens approximately 4.9 miles (8 km) southeast of the site.

The two non-potable abstractions listed in Table 8 are reportedly for cooling purposes therefore the requirements for water quality for this purpose is potentially limited to consideration of physico-chemical properties (such as total suspended solids, pH, temperature, or similar), so that the abstracted water does not block or damage equipment associated with or inhibit the functionality of the cooling systems.

3.6 Hydrology

The ToR (Wood, 2021) details that the porous nature of the limestone bedrock and the flat topography of the Grand Cayman results in a lack rivers or streams across the island. Constructed mosquito-control channels transverse the local area and discharge into North Sound approximately 2,460 ft (750 m) northeast of the Site. The closest channel ('northern channel') runs west to east along the northern boundary of the proposed development. The northern channel is fringed with mangroves and is culverted below Esterly Tibbetts Highway to the west of the Site. Other channels are present around the GTLF to the west of the Site and discharge into the 'northern channel'.

The ToR (Wood, 2021) also states that the water level in the channels and the North Sound fluctuate with the tide. The tidal variation in the North Sound recorded by CIG (1992) was in the order of 0.8 ft (0.24 m). Data from an Intergovernmental Oceanography Commission (IOC) sea level monitoring station at George Town indicates the tidal variation in North Sound at the time of water sampling on 14 April 2015 was approximately 1 ft (0.3 m). The depth of the canals is such that they will likely be in hydraulic conductivity with groundwater.

3.6.1 Surface water quality

The ToR (Wood, 2021) states that surface water quality in the 'northern channel' and the North Sound near the Site has been monitored by DEH between 2006 and 2013 and by Amec Foster Wheeler in 2015. The data is provided in full in Amec Foster Wheeler (2016) and summarised in Table 9. The data shows that the 'northern channel' is potentially

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

affected by leachate from GTLF, which acts as a source of contaminants, including ammonia, orthophosphate, Biological Oxygen Demand (BOD) and Chemical Oxygen Demand (COD), entering the North Sound. A review of available data indicates that there is apparently a relatively rapid dilution/dispersion of the discharge within North Sound.

Table 9 Summary of general surface water quality surrounding the Site. [Source: Wood, 2021]

Substance	Unit	Northern Channel			North Sound		
		Min	Mean	Max	Min	Mean	Max
Ammonia	mg/l	0.32	4.26	13	0.51	0.81	1.1
Orthophosphate	mg/l	0.03	0.13	0.44	<0.015	0.039	0.052
COD	mg/l	23	1,902	11,000	200	200	200
pH	-	7.34	7.56	8.25	n.m.	n.m.	n.m.
Specific Conductance	umhos/ cm	15,000	52,000	130,000	n.m.	n.m.	n.m.
BOD	mg/l	2.5	11	36	<2.0	-	3
Diesel Range Organics [C10-C28]	mg/l	0.046	0.119	0.33	-	-	0.048
GRO-C6-C10	mg/l	<0.047	-	-	n.m.	n.m.	n.m.

In addition to the groundwater data (Section 3.5.1), DART also provided GHD with surface water quality data, whereby concentrations of a suite of contaminants have also been analysed throughout the sampling period. Their locations are shown in Figure 3. The most recent round of sampling was conducted by DEH as per their monitoring schedule/plan. Table 10 summarises the concentrations of contaminants detected across the Site and surrounding area in comparison with relevant CCTLs. The data discrepancies detailed in Section 3.5.1 apply to this data set and are considered in the interpretation of data.

Table 10 Summary of surface water contamination surrounding the Site between 2006 and December 2022. [Source: Appendix A]

Alpha-BHC	µg/L	0.005	25	100	71	0.000007	1	0.114

Notes: * Predominantly due to LoD exceeding CCTL, however some actual exceedances have been recorded in samples where the LoDs are lower.

Cells shaded red indicate an exceedance of the CCTL, cells shaded orange indicate exceedances where the LoD exceeds the CCTL, cells shaded green indicate that concentrations fall below the CCTL.

Site-wide CCTL exceedances in turbidity have been identified, being particularly consistent in the north and northwest of the Site, which may be explained by the location of the Site being within the transition zone where considerable mixing of groundwater and saltwater occur.

VOCs acrylonitrile, and 1,2,3-trichloropropane were found to exceed their respective CCTLs. In many samples it is suspected that this is caused by data reporting in a different unit, and in other samples it may potentially be due to the LoD exceeding the CCTL.

Vinyl chloride was identified above the CCTL in SW12 toward the south of the Site, also exhibiting a sharply rising pattern within the three data points obtained for leachate between July 2020 and December 2022. Due to the assumed north/north-easterly groundwater flow from the Site to the Northern Channel and North Sound, it is unlikely that these exceedances are related. However, these results, in particular those associated with the December 2022 monitoring round, may be caused by data reporting in a different unit.

Arsenic concentrations were noted to be consistent within the western area of the Site. A significant increase in concentration of arsenic was identified in this location during the December 2022 round of sampling, which is consistent with increases in chromium (hexavalent), magnesium, and zinc in the same locations. This may indicate a potential relationship between the substances and their potential source. The exceedances of arsenic and chromium (hexavalent) may potentially be associated with the arsenic containment cell (detailed within the Land Quality Assessment of this EIA), located in the centre/south of the Site since circa 2005, due to presence of timber treated with chromated copper arsenate (CCA) preservatives. However, it is considered more likely that many of these exceedances, in particular those associated with the December 2022 monitoring round, may be caused by data reporting in a different unit. This may also explain many of the exceedances for other substances including antimony, cadmium, copper, iron, lead, nickel, silver, thallium, and mercury.

Consistent exceedances of lead were identified in SW7 (north of the Site) alongside some isolated exceedances across the wider Site area during the older sampling periods between 2006 and 2013. Zinc concentrations were also found to exceed the CCTLs in samples obtained from the Site drains.

Several exceedances of pesticides 4,4'-DDD, 4,4'-DDE, and alpha-BHC were also noted in several samples. Whilst this could have been associated with treated timber within the arsenic containment cell, all sample data falls below the LoD, therefore analysis of the exceeding data remains inconclusive.

GHD undertook a flood risk assessment for the proposed development, which included calibration to the measurements taken during Hurricane Ivan, then simulating Category 2, 3 and 5 cyclone events. The results of the assessment show

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

that the most severe storm surge conditions occur in the interior of the north bay, corresponding with previous models. Category 5 conditions result in the largest storm surges, peaking at 9.5 ft (2.9 m) within the North Bay, and Category 2 and 3 conditions produce similar peak water surface elevations of approximately 5.6 and 5.9 ft (1.7 and 1.8 m) respectively. The severity of the surges on the shoreline are reduced due to the generally steep bathymetry surrounding the majority of Grand Cayman, however, the North Bay area is susceptible to significant surge effects due to shallow bathymetry and semi-enclosed geometry within this region. In the event of an extreme rainfall event occurring in combination with a coastal storm surge, flooding is likely to be exacerbated.

3.7 Flood risk

As stated in the ToR (Wood, 2021), surface water flooding occurs as a result of rainfall intensity exceeding the capacity of local drainage and infiltration, causing water to flow overland. This is considered a potential hazard following heavy rainfall events. In the Cayman Islands, heavy rainfall typically only takes place for several hours, which, at worst, reportedly causes moderate flooding in some low-lying regions of the islands. This is due to the rapid infiltration of water enabled by the island's surface, which mostly comprises a limestone outcrop or very thin and porous limestone soils. However, if a tropical depression settles over the island, it can rain for a period of several days with surface water flooding resulting in severe problems.

The Cayman Islands has experienced a total of 74 tropical storms and hurricanes over the period of 1852 to 2008 (156 years), with nine major storms of Category three or higher. In September 2004, Hurricane Ivan reportedly caused sustained winds of up to 155 mph (249 km/h), producing storm surges of 9.5 ft (2.9 m) and wave heights of greater than 26 ft (7.9 m) that flooded large coastal areas and deposited large amounts of sediment onshore (Wood, 2021).

No delineated floodplain mapping was found for the Cayman Islands. However, the Site, like much of Grand Cayman, is low-lying which indicates that tidal flooding and hurricane/tropical storm-associated flooding are significant potential hazards. The flood zones resulting from hurricanes according to hurricane categories on the Saffir-Simpson Scale are shown on Figure 4, as detailed in the ToR (Wood, 2021). Exposure scores for flood hazards were determined by Novelo-Casanova and Suarez based on a) flood distribution areas during Hurricane Ivan, and b) topographic elevation and potential for flooding, as follows:

– Level 5 (very high exposure score) as shown on Figure 4, 'a' was assigned to zones where coastal flooding and wave action are the highest during Category 1 and 2 hurricanes which, on average, hit the Cayman Islands every 2.33 years.
– Level 4 (high exposure) was applied to Category 3 flood areas (Figure 4 'b') with hurricanes of this magnitude typically hitting the islands once every 9.1 years).
– Level 3 (moderate exposure) given to flood areas associated with hurricane Categories 4 and 5 (Figure 4 'c') that take place approximately every 100 years.

This shows that the Site is within an area of very high exposure to hurricanes and associated flooding and storm surge. Storm surges combined with wave action are responsible for much of the damage usually caused by hurricanes, especially in large, low-lying coastal settlements. In addition to causing flooding and damage to coastal structures, storm surges may also cause flooding further inland through the blockage of the outfalls of drainage systems.

GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

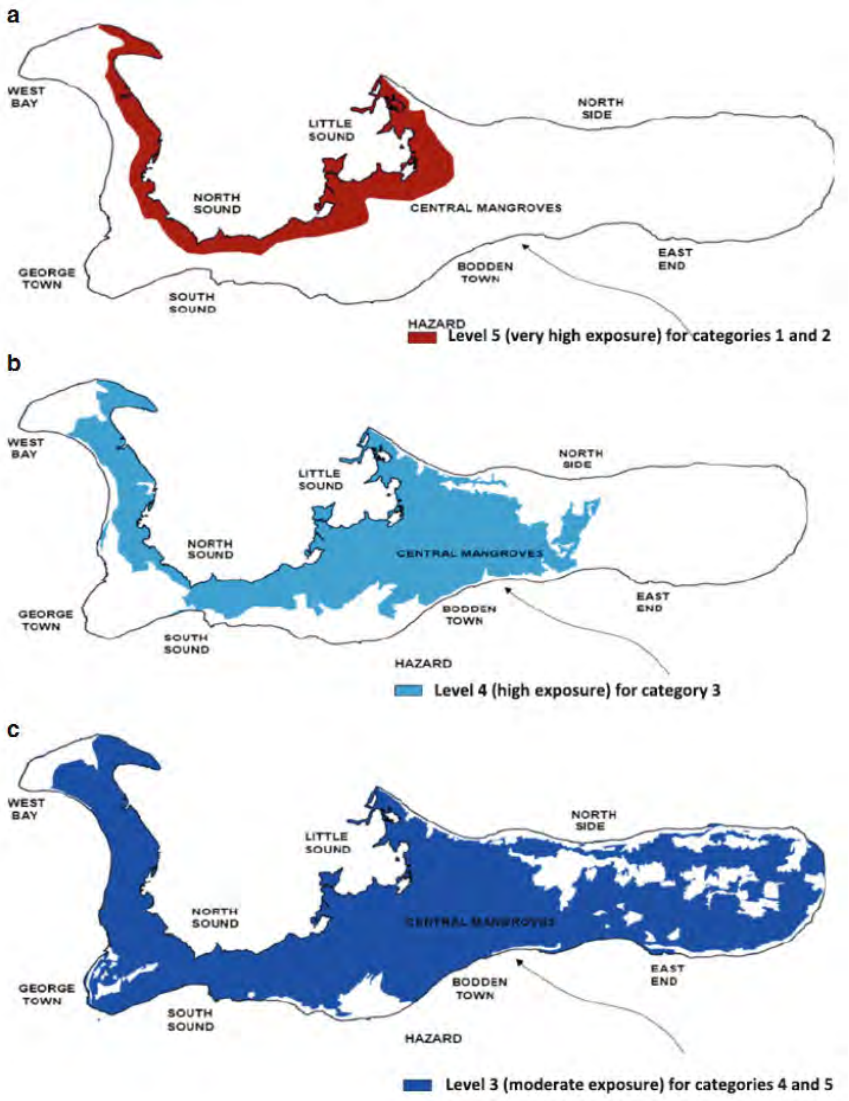

Figure 4 ***Level of exposure to due to flooding from hurricanes: a) Hurricane categories 1 and 2, b) Hurricane category 3, c) Hurricane categories 4 and 5. The arrow indicates the direction of approach of the hurricane. [Source: Novelo-Casanova and Suarez, 2010; Wood, 2021]***

GHD undertook a flood risk assessment for the proposed development, which included calibration to the measurements taken during Hurricane Ivan, then simulating Category 2, 3 and 5 cyclone events. The results of the assessment show that the most severe storm surge conditions occur in the interior of the north bay, corresponding with previous models. Category 5 conditions result in the largest storm surges, peaking at 9.5 ft (2.9 m) within the North Bay, and Category 2 and 3 conditions produce similar peak water surface elevations of approximately 5.6 and 5.9 ft (1.7 and 1.8 m) respectively. The severity of the surges on the shoreline are reduced due to the generally steep bathymetry surrounding the majority of Grand Cayman, however, the North Bay area is susceptible to significant surge effects due to shallow bathymetry and semi-enclosed geometry within this region. In the event of an extreme rainfall event occurring in combination with a coastal storm surge, flooding is likely to be exacerbated.

3.8 Protected areas

According to the ToR (Wood, 2021) the closest proposed international designated (proposed Ramsar) sites are located approximately 4.5 km (2.75 miles) to the east (Central Mangrove Wetland, Little Sound, Ponds and associated Marine Zones) and 7.5 km (4.75 miles) to the north (Barkers Wetland) of the Site. The Central Mangrove Wetland, Little Sound,

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Ponds and associated Marine Zones comprise pristine mangrove wetlands supporting important habitats, marine invertebrates and internationally important populations of migratory birds. Barkers Wetland is a continuum from coral reef to coastal forest and mangrove supporting endangered marine and terrestrial reptiles, breeding and migratory birds as well as important invertebrates and endemic fish.

The Cayman Islands has a network of marine protected areas. There are three categories of marine parks for Grand Cayman:

– Environmental zone: in which prohibited activities include the removal of any form of marine life, the use of anchors, entry into the water and exceeding a speed of five knots.
– Replenishment zone: where the removal of conch and lobster is prohibited, and fishing methods restricted.
– Marine park zone: in which marine life is protected and anchoring forbidden, except in certain circumstances.

The closest marine protected area to the Site is the Marine Reserve on the west coast which comprises the Seven Mile Beach. The North Sound to the east of the Site also contains marine protected areas (Replenishment and Environmental zones). The closest nationally important terrestrial areas to the Site include the Mangrove Buffer Zone near the west coast and three Terrestrial Protected Areas between 1.4 km (0.9 miles) and 2.5 km (1.5 miles) to the north.

3.9 Future Baseline

Land use changes, and particularly climate change, could affect baseline conditions at the Site in the future.

Climate change could affect the amount, intensity and duration of rainfall, temperature and evapotranspiration, occurrence of extreme weather (hurricanes) and amount and rate of sea level rise.

As outlined in the ToR (Wood, 2021), estimates of future sea-level rise within the Caribbean in the Model for the Assessment of Greenhouse-gas Induced Climate Change (MAGICC) indicates an increase of 12 cm (0.4 ft) to 80 cm (2.6 ft) in sea levels by 2100 from a 1990 baseline. This range encompasses the conservative estimates by the Intergovernmental Panel on Climate Change (IPCC) for global sea-level rise and represents a rise of approximately 0.14 cm to 0.91 cm (0.05 inch to 0.35 inch) per year. The Cayman Islands are amongst those islands showing regional variation in rainfall projections, with a decrease of between 10 and 50 mm in annual rainfall totals predicted between 2011 and 2099 (National Climate Change Committee, 2011). This could change the hydrological characteristics of the Site and wider catchment areas over time.

With respect to groundwater and surface water quality at the Site and the surrounding area, analysis of laboratory results using a highly precautionary approach (Section 3.5.1) suggest that groundwater and surface waters are already affected to some extent. These are believed to be primarily affected by emissions from GTLF, the closure of which is only possible if ISWMS proceeds at the Site providing an alternative waste disposal option. In the absence of ISWMS, it is likely that operation of the GTLF would be prolonged and, even if operational controls of leachate were improved, the associated emissions are likely to continue to impact groundwater and surface water quality over a prolonged period.

Local pollution incidents unrelated to the Site could also cause changes in the water quality within the proposed development Site and wider catchment.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

4. Impact Assessment

4.1 Potential effects

The potential hydrology (including flood risk) and hydrogeology effects associated with the proposed development are summarised in Table 11. A number of these are sourced from the ToR (Wood, 2021).

When considering potential impacts the following design specifications for the proposed development were considered with regards to water supply and wastewater management which will require the necessary consents and permits from the relevant authority:

– Potable water supply will be sourced from the municipal water supply provided by the Cayman Water Authority.
– Cooling water for the Energy Recovery Facility (ERF) will be sourced from groundwater abstractions located within the Project Site, abstracted from approximate depth of 51 to 149 feet/130 (15.5 to 45.4 m).
– Following the ERF cooling cycle, cooling water will be discharged to the ground via discharge wells located within the Project Site, at discharge depth at circa 250 to 400 feet (76 to 121 m).
– Sewage and wastewater from toilet blocks will be disposed of either to mains sewer and the neighbouring wastewater treatment plant (subject to agreement for the Operator) or via septic tank to groundwater.

Table 11 Potential hydrology (including flood risk) and hydrogeology effects

Activity	Potential Effect	Receptor
Temporary dewatering associated with the excavation of the foundations for infrastructure	Localised and temporary decline in groundwater levels and baseflows, deterioration in groundwater quality via induced saline intrusion	• Aquifers • Surface waters (North Sound & Mosquito control canals) • Groundwater abstractions
Temporary storage/stockpiling of materials	Change surface water drainage patterns and locally increase flood risk	• Site infrastructure, staff, and visitors • Surface waters (North Sound & Mosquito control canals)
Soil compaction and introduction of areas of hardstanding	Reduce infiltration recharge and groundwater levels and baseflows	• Aquifers • Surface waters (North Sound & Mosquito control canals) • Groundwater abstractions
	Increase surface water runoff and sediment-loading	• Surface waters (North Sound & Mosquito control canals)
	Increase surface water runoff and flood risk	• Surrounding land infrastructure, staff, and visitors
Groundwater abstraction for on-Site non-potable supply for ERF cooling, compost irrigation and general Site maintenance)	Localised decline in groundwater levels and baseflows, further deterioration in groundwater quality via induced saline intrusion, increase in local groundwater temperature.	• Aquifers • Surface waters (North Sound & Mosquito control canals) • Groundwater abstractions
Disposal of wastewater generated at the Site (including potential sanitary effluent, facility wash water, Composting Area runoff and non-contact ERF cooling water)	Deterioration in groundwater and baseflow quality	• Aquifers • Surface waters (North Sound & Mosquito control canals) • Groundwater abstractions • Subsurface infrastructure

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. Activity	Potential Effect	Receptor
Disposal of landfill leachate from the RWL	Deterioration in groundwater and baseflow quality	• Aquifers • Surface waters (North Sound & Mosquito control canals) • Groundwater abstractions • Subsurface infrastructure
Disturbance of existing contamination (discussed in the Land Quality Assessment of this EIA)	Exposure (and potential spread) of contaminated soils at the Site surface and release of runoff, deteriorating water quality	• Aquifers • Surface waters (North Sound & Mosquito control canals) • Groundwater abstractions • Subsurface infrastructure
Potentially contaminative activities on-Site	Release of pollutants directly (e.g., spillages) or indirectly (via surface water runoff), leading to deterioration in surface water and groundwater quality	• Aquifers • Surface waters (North Sound & Mosquito control canals) • Groundwater abstractions • Subsurface infrastructure
Tidal flooding, surface water flooding and extreme weather and climate change-induced flood events	Multiple effects e.g., sediment-loading release of pollutants, flooding, mobilisation of contaminants off-Site by flood water	• Aquifers • Surface waters (North Sound & Mosquito control canals) • Groundwater abstractions • Site infrastructure, staff, and visitors
Failure of landfill cap or composite liner (*e.g.* due to flawed engineering, extreme weather events or sea-level rise)	Ingress of rainwater resulting in uncontrolled releases of leachate to the surrounding ground and groundwater	• Aquifers • Surface waters (North Sound & Mosquito control canals) • Groundwater abstractions • Subsurface infrastructure
Inappropriate disposal of additional wastes during emergency situations (*e.g.* hurricane or earthquake debris)	The composition of such wastes is unknown but may result in unsuitable materials being stockpiled that could result in unforeseen leachate issues that could affect surface waters and groundwater	• Aquifers • Surface waters (North Sound & Mosquito control canals) • Groundwater abstractions • Subsurface infrastructure

4.1.1 Groundwater abstractions

The cooling water for the proposed ERF will be sourced from groundwater using abstraction wells within the Project Site. Following the ERF cooling cycle, this groundwater (which will be warmer than ambient groundwater temperature) will be discharged to the ground via discharge wells located within the Project Site.

R. C. Minning & Associates Inc (2023) undertook a hydrogeological investigation and modelling to investigate the potential impacts of the proposed ERF 'cooling water' wells relative to each other (abstraction and discharge points) and existing groundwater users in proximity of the development. It incorporated site-specific geological and hydrogeological data as well as available geological and hydrogeological information for the region. Groundwater modeling was undertaken to simulate the groundwater flow system and to simulate future heat and groundwater transport scenarios associated with the installation and operation of the cooling water system.

The R. C. Minning & Associates Inc (2023) assessment was undertaken on the basis of an assumed groundwater abstraction rate for the geothermal cooling system of 11,000 gpm (gallons per minute) via four abstraction wells, each

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

yielding 2, 750 gpm. The assumed abstraction well depth was ~51ft to ~149ft below ground surface with injection (discharge) via three wells to a depth of ~250ft to ~400ft below ground surface.

Modelling by R.C. Minning & Associates Inc (2023), alongside previous studies and operational history within the area, indicated that this abstraction is likely to be sustainable, with limited drawdown of groundwater levels anticipated once the system is in operation. The volumes of abstracted water were anticipated to be recharged via horizontal groundwater flow from the North Sound, alongside periodic discharge from on-Site stormwater drainage into the abstraction zone coupled with local precipitation. Recharge via horizontal groundwater flow from the North Sound indicates that saline intrusion could occur, however, the groundwater in the area is brackish to saline, with saline conditions (>10,000 mg/L TDS) occurring in proximity to the 'northern channel or North Sound (refer Section 8.4.5).

The findings of the hydrogeological investigation and modelling were as follows:

– Limited drawdown of the groundwater levels will occur when the ERF cooling water system is in operation.
– Limited warming of the groundwater (0.1°C to 0.6°C) in the cooling water system abstraction zone (at the site), due to the hydrogeological characteristics and the operation of the cooling water system, i.e., low vertical permeability and injection (discharge) at a significantly lower depth and geology (between ~-250 and ~-400 ft below ground surface).
– No impact on any adjacent groundwater abstractions associated with the proposed ERF cooling water system.
– None of the injected warm water from the ReGen facility reached the Caribbean Sea, North Sound, the residential canals or nearby water users in the modelled simulations.

The hydrogeological investigation also considered the potential for 'short-circuiting' by two pathways:

– Vertical migration from the injection zone upward into the abstraction zone via joint and fracture systems, i.e., high vertical permeabilities. This was considered unlikely due to:
    - the vertical difference in depths between injection and abstraction wells, as well as low permeability with fractures rarely evident in the strata above -350 feet.
    - groundwater flow is primarily horizontal via intra formational pathways such as bedding plains and solution channels.
    - Empirical support for minimal vertical hydraulic communication between these zones and operation of similar cooling water systems which indicate that the vertical permeability of the 150 – 200 ft BGS layer is sufficiently low to prevent short circuiting.
– inadequate well construction (particularly the injection wells).
    - To be mitigated through appropriate grouting in the annulus to create a between the well casing and the surrounding rock.

The R. C. Minning & Associates Inc (2023) is provided in **Appendix B.**

4.2 Embedded Measures

The currently proposed layout, design, and operation of the ISWMS is described in Chapter 4 of this EIA and includes consideration of potential hydrology and hydrogeology effects, explicitly or otherwise. Some of these proposed mitigation measures are outlined in more detail in the sections below.

4.2.1 Leachate management

According to Chapter 4, "*the Residual Waste Landfill will be an engineered facility with a composite liner, leachate containment, leachate treatment, environmental controls and monitoring*". It will be designed, constructed and/or

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

operated in line with relevant modern US standards, which should include procedures to manage landfill by-products including leachate, dusts, odours, and landfill gas, such as:

- Resource Conservation and Recovery Act (RCRA) (Sub-Title D Non-Hazardous Rules and Sub-Title C Hazardous Rules)
- RCRA Subtitle D (258) Seismic Design Guidance for Municipal Solid Waste Landfill Facilities.
- 40 Code of Federal Regulations:
  - Part 258 – Criteria for Municipal Solid Waste Landfills
  - Part 264 – Standards for Owners and Operators of Hazardous Waste Treatment, Storage, and Disposal Facilities
  - Part 265 – Interim Status Standards for Owners and Operators of Hazardous Waste Treatment, Storage, And Disposal Facilities
- Standards for the GTLF design (remediated as part of the ISWMS project):
  - Florida Administrative Code No. 62-701.500: Landfill Operation Requirements
  - Florida Administrative Code No. 62-701.600: Landfill Final Closure

The nature of the residual waste (principally post-combustion residues from the ERF) will limit its leachability and putrescibility but, if fully complied with, the standards stipulate requirements for leachate emissions to be mitigated appropriately. This would therefore reduce the likelihood of deterioration in surface water or groundwater quality via pollutant (leachate) release.

The Landfill Facility design will incorporate pollution control features (e.g., leachate extraction wells, transmission pipework and a sequencing batch reactor type leachate treatment plant) to collect and treat leachate produced within the landfill cell(s). The leachate will be treated on site and potential reuse of the effluent for dust suppression purposes will be considered. The effluent quality will be suitable for discharge from the Site in compliance with local environmental licence requirements.

Subject to the quality of the effluent from the leachate treatment plant, in addition to reuse on site, disposal mechanism could include to the off-site and adjacent wastewater treatment plant (subject to agreement with Water Authority Cayman) or disposed of on-site via deep well injection. The quality of the leachate post treatment will be assessed as part of the detailed design of the treatment plant.

The following features are proposed for the leachate management system:

- Leachate from the waste bunker will be pumped out in accordance with the expected composition of the waste, into a suitable containment system followed by treatment if necessary.
- A leachate drainage network will be installed, with all roads and operating areas to be instated and maintained to ensure that no damage occurs.
- Storm water will also be collected through the leachate collection system.
- Leachate that has been recirculated will be sprayed over the composting windrow, in the event that the moisture content must be raised. It will also be used for dust suppression purposes for the non-capped areas of the facility via tractor and bowser.
- Clean surface water from non-active areas will be prevented from making contact with the leachate in the active areas via temporary internal bunds and storm flaps to prevent contamination of this water.
- A leachate treatment plant will be developed to receive, treat, and dispose of leachate from the landfill facility, prior to the landfill facility becoming operational. The volume of generated leachate will determine the capacity of the leachate treatment plant and the ability to balance with the volumes of recirculated leachate required for dust suppression. Where volumes of recirculated leachate are insufficient for the demand, grey water shall be used instead.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

4.2.2 Storage and material handling

According to Chapter 4, "*Facility designs include consideration of laydown areas which will be set aside for the storage of construction materials and waste management activities and located away from potential contaminant pathways.*". This would therefore reduce the likelihood of construction materials and wastes becoming a potential pollutant source within a potential contaminant pathway, reducing the likelihood of deterioration in surface water or groundwater quality via pollutant release.

This section in Chapter 4 however does not consider the effect of changes to surface water drainage patterns, and therefore could still potentially contribute to an increase in local flood risk.

4.2.3 Facility design standards

As noted in Chapter 4, each of the ISWMS facilities will be designed to a still water elevation of 8 ft above mean sea level (AMSL), based on Hurricane Ivan (a 1 in 100 year return period) records and US Federal Emergency Management Agency (FEMA) guidance has been used to arrive at Base Flood Elevation (BFE) of +12 ft (3.7 m) AMSL and Design Flood Elevation (DFE) of +13 ft (4.0 m) AMSL. Drainage systems will be designed to manage the impacts of extreme weather conditions and reduce risk of flooding and will comply with all applicable building design codes and regulations.

4.2.4 Stormwater management

A general site drainage system to manage surface water run-off from non-operational areas of the Site has been developed and is described in Chapter 4. The design of the Site's drainage system incorporates pollution control features and system divisions to isolate specific areas as appropriate.

4.3 Assessment of effects

The potential significance of the effects identified in Section 4.1 have been assessed in line with the methodology outlined in Section 2.3 in order to identify potentially significant effects in the absence of mitigation beyond that considered integral to the design (embedded measures) (see Table 12).

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 12 Significance assessment of potential water-related effects in the absence of mitigation (except for embedded design measures)

Activity	Receptor	Value	Magnitude	Significance	Rationale
Temporary dewatering associated with the excavation of the foundations for infrastructure	Aquifer quality	Medium	Low	Minor	As aquifers on Grand Cayman are of high salinity and high yield, they are not considered to support human health without desalinisation and treatment to achieve drinking water quality standards. Therefore, a deterioration in quality due to saline intrusion is not considered a Significant Effect.
	Surface waters (North Sound & Mosquito control canals)	Medium	Low	Minor	While the North Sound surface waters support local economic activity and recreation, saline intrusion via hydraulic connectivity is not considered to significantly deteriorate quality. As groundwater flow acts as a baseline flow for surface waters, there may be a temporary slight decline in water levels, however this is not considered to be significant.
	Groundwater abstractions	Medium	Low	Minor	As dewatering works will be transient, and groundwater abstractions likely being unnecessary for the development at this stage, the effect on groundwater abstractions and therefore not considered to be significant. For off-Site abstractions identified, these are 0.6 miles (potable water supply) and 0.5 miles (cooling water) from the proposed development and likely abstract at significant depth (100 feet or 30.5 m depth for potable water, from 70 feet or 21 m depth for CUC cooling water) and therefore not likely to be impacted by the shallow and transient anticipated groundwater disturbance taking place during construction. This is not considered a Significant Effect.
Temporary storage/stockpiling of materials	Site infrastructure, staff, and visitors	Medium	Low	Minor	As described in Chapter 4, drainage systems will be designed to manage the impacts of extreme weather conditions and reduce risk of flooding and will comply with all applicable building design codes and regulations. Further a general site drainage system to manage surface water run-off from non-operational areas of the Site has been developed and is described in Chapter 4. This is not considered a Significant Effect.
	Surface waters (North Sound & Mosquito control canals)	Medium	Low	Minor	Localised flooding would be unlikely to cause significant effect to surface waters located off-site, due to likely low volumes of flood water alongside the effects being temporary.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Activity	Receptor	Value	Magnitude	Significance	Rationale
Soil compaction and introduction of areas of hardstanding	Aquifer quality	Medium	Low	Minor	As aquifers on Grand Cayman are of high salinity and low yield, they are not considered to support human health without desalinisation and treatment to achieve drinking water quality standards. A reduction in groundwater levels due to slight increase in hardstand surfaces at the site is considered unlikely to result in a significant effect to users. Surface water management measures may also enable infiltration in some areas of the Site, minimising the potential reduction in groundwater levels.
	Surface waters (North Sound & Mosquito control canals)	Medium	Very low	Minor	As described in Chapter 4, drainage systems will be designed to manage the impacts of extreme weather conditions and reduce risk of flooding and will comply with all applicable building design codes and regulations. Further a general site drainage system to manage surface water run-off from non-operational areas of the Site (as well as associated pollution management measures) has been developed and is described in Chapter 4. This is not considered a Significant Effect.
	Groundwater abstractions	Medium	Low	Minor	Reduced infiltration could locally result in a minor and localised change to groundwater recharge. However, it is considered unlikely to significantly affect water table levels outside of the site and, therefore, there is likely to be limited effect on groundwater abstractions identified within 1.2 miles of the proposed development. The proposed abstraction of water for on-site cooling purposes is also unlikely to be impacted due to the depth of the proposed abstraction (51 to 149 feet below ground surface). This is not considered a Significant Effect.
	Surrounding land infrastructure, staff, and visitors	High	Very low	Minor	As described in Chapter 4, drainage systems will be designed to manage the impacts of extreme weather conditions and reduce risk of flooding and will comply with all applicable building design codes and regulations. Further a general site drainage system to manage surface water run-off from non-operational areas of the Site has been developed and is described in Chapter 4. This is not considered a Significant Effect.

Activity	Receptor	Value	Magnitude	Significance	Rationale
Groundwater abstraction for on-Site non-potable supply for ERF cooling, compost irrigation and general Site maintenance)	Aquifer quality	Medium	Medium	Minor	As aquifers on Grand Cayman are of high salinity, they are not considered to support human health without desalinisation and treatment to achieve drinking water quality standards. Therefore, a deterioration in quality via potential saline intrusion associated with groundwater abstraction is not considered a Significant Effect on groundwater quality.
	Surface waters quality (North Sound & Mosquito control canals)	Medium	Low	Minor	While the North Sound surface waters support local economic activity and recreation, saline intrusion via hydraulic connectivity is not considered to significantly deteriorate quality in surface water (due to groundwater already being saline). Abstraction modelling by R.C. Minnings and Associates Inc (2023) indicates that the proposed abstraction rate of 11,000 gpm is unlikely to affect surface waters, due to the limited extent of drawdown identified from the groundwater.
	Groundwater abstractions	Medium	Low	Minor	An assessment of the impact of the proposed abstraction rate of 11,000 gpm for the proposed ERF cooling water suggests that there is limited drawdown, is unlikely to significantly affect water table levels and therefore there is likely to be limited effect on groundwater abstractions identified within 1.2 miles of the proposed development.
Disposal of wastewater generated at the Site (including potential sanitary effluent, facility wash water, Composting Area runoff and	Aquifer quality	Medium	Low	Minor	As aquifers on Grand Cayman are of high salinity and low yield, they are not considered to support human health or economic activity without desalinisation and treatment to achieve drinking water quality standards. The modelled groundwater discharge of cooling water by R.C. Minnings and Associates Inc (2023) suggests thatthere is limited impact to groundwater in terms of temperature increase. Therefore, a deterioration in quality is not considered a Significant Effect.

GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Activity	Receptor	Value	Magnitude	Significance	Rationale
non-contact ERF cooling water)	Surface waters (North Sound & Mosquito control canals)	**Medium**	**Medium**	**Moderate**	**The North Sound surface waters support local economic activity and recreation, and marine protected areas, therefore a deterioration in quality from potential contamination from discharge of wastewater to groundwater (or quality impacted groundwater in connectivity with surface waters) could negatively affect surface water users. The potential disposal of sanitary wastewater to shallow groundwater via septic tanks would be considered the potential source. This is considered a Potentially Significant Effect and depends on the potential contaminant properties and concentrations as to how much this could effect water quality. This also depends on whether the mains sewerage disposal route can be used for sanitary wastewater discharge.** The disposal of non-sanitary waste (e.g. cooling water) is of sufficient depth (circa 250-400 feet) to be considered to not impact surface water quality.
	Groundwater abstractions	Medium	Low	Minor	Groundwater abstractions (on-site and off-site) are likely to be deep in the limestone aquifer, at a depth considered unlikely to be impacted by either discharge from septic tanks (to shallow groundwater) or from the deeper (circa 250-400 feet) discharge of cooling water. Therefore, a deterioration in groundwater quality is not considered a Significant Effect on the off-site abstractions or proposed on-site abstractions (for cooling water purposes).
	Subsurface infrastructure at the site	**Medium**	**Medium**	**Moderate**	**Potential contamination of groundwater with elevated concentrations of contaminants, including sulphate, may compromise the structural integrity of concrete infrastructure (such as foundations) depending on the concrete grade used within the development. This could cause significant effect to the Site infrastructure.**
Disposal of landfill leachate from the RWL	Aquifer quality	Medium	Low	Minor	Assuming compliance with the leachate management procedures, any leachate emissions would be managed and mitigated appropriately and would therefore reduce the likelihood of water quality deterioration. Also, as aquifers on Grand Cayman are of high salinity and they are not considered to support human health without desalinisation and treatment to achieve drinking water quality standards. Therefore, a deterioration in quality is not considered a Significant Effect.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Activity	Receptor	Value	Magnitude	Significance	Rationale
	Surface waters quality (North Sound & Mosquito control canals)	Medium	Low	Minor	The North Sound surface waters support local economic activity and recreation, and marine protected areas, therefore a deterioration in quality from potential contamination from landfill leachates could negatively effect surface water users. However, leachate management procedures reduce the likelihood of this occurring. This is therefore considered not Significant.
	Groundwater abstractions	Medium	Low	Minor	Leachate management procedures reduce the likelihood of leachate reaching and impacting groundwater quality. In the event of an uncontrolled release of leachate to groundwater then this is considered unlikely to impact on-site or off-site groundwater abstractions due to a combination of depth of on-site abstraction (circa 51-149 feet), as well as depth of abstraction and distance to the off-site abstractions. Any uncontrolled release of leachate is likely to be limited in duration (i.e. temporally limited) due to mitigation measures that will be documented in the detailed design of the ISWMS facility and associated environmental management plans. This is therefore considered not Significant.
	Subsurface infrastructure	Medium	Low	Minor	Potential contamination of groundwater with elevated concentrations of sulphate may compromise the structural integrity of any concrete infrastructure (such as foundations) depending on the concrete grade used within the development. Any uncontrolled release of leachate is likely to be limited in duration (i.e. temporally limited) due to mitigation measures that will be documented in the detailed design of the ISWMS facility and associated environmental management plans. This is therefore considered not Significant.
Disturbance of existing contamination (discussed in the Land Quality Assessment of the EIA)	Aquifer quality	Medium	Medium	Moderate	**Despite desalinisation and treatment being required to achieve drinking water quality standards, groundwater within aquifers on Grand Cayman is abstracted to ultimately support human health as well as economic activity. Deterioration in quality is therefore considered a Potentially Significant Effect.**
	Surface waters quality (North Sound & Mosquito control canals)	**Medium**	**Medium**	**Moderate**	**While the North Sound surface waters support local economic activity and recreation, disturbance of contamination on-site has the potential to migrate via surface water runoff or shallow groundwater and subsequent discharge to surface water.**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Activity	Receptor	Value	Magnitude	Significance	Rationale
	Groundwater abstractions	Medium	Low	Minor	The disturbance of contaminated land is considered unlikely to impact on-site or off-site groundwater abstractions due to a combination of depth of on-site abstraction (circa 51-149 feet), as well as depth of abstraction and distance to the off-site abstractions. The potential effect is therefore not considered significant.
	Subsurface infrastructure	**Medium**	**Medium**	**Moderate**	**While potential contamination of groundwater is considered unlikely, and may not result in elevated sulphate concentrations, potential contamination of groundwater with elevated concentrations of Sulphate may compromise the structural integrity of any concrete infrastructure (such as foundations) depending on the concrete grade used within the development. This is a general consideration for the whole Site.**
Potentially contaminative activities on-Site	Aquifer quality	Low	Medium	Minor	As aquifers on Grand Cayman are of high salinity and low yield, they are not considered to support human health or economic activity without desalinisation and treatment to achieve drinking water quality standards. The groundwater quality is considered to potentially already be impacted by GTLF operations. Therefore a deterioration in quality is not considered a Significant Effect.
	Surface waters quality (North Sound & Mosquito control canals)	**Medium**	**Medium**	**Moderate**	**The North Sound surface waters support local economic activity and recreation, and marine protected areas, therefore a deterioration in quality from potential contamination from Site activity (from surface runoff or migration via groundwater) could negatively affect surface water users. This is considered a Potentially Significant Effect and depends on the potential contaminant properties within the leachate and other sources and their respective concentrations.**
	Groundwater abstractions	**Medium**	**Low**	**Minor**	Contaminating activities on site is considered unlikely to significantly impact on-site or off-site groundwater abstractions due to a combination of depth of on-site abstraction (circa 51-149 feet), as well as depth of abstraction and distance to the off-site abstractions. The potential effect is therefore not considered significant.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. 4.4 Summary of findings

An assessment of the significance of each of the potential hydrological and hydrogeological effects identified with respect to the proposed development are presented in Table 12. This identified the following potentially significant (moderate or major) effects:

1. Deterioration in local water quality as a result of contamination associated with potential wastewater disposal (sanitary waste disposed via septic tank) may affect recreational users of surface waters, in particular for the North Sound. Subsurface concrete infrastructure could also be affected, depending on the contents of the wastewater and the grade of concrete used.
2. Deterioration in aquifer quality as a result of contamination associated with disturbance of existing known contamination may affect groundwater abstracted for drinking water use, despite being subject to treatment and desalination prior to use.
3. Deterioration of surface water quality resulting from contamination caused by disturbance of existing contamination on-site. Subsurface concrete infrastructure could also be affected, depending on the contaminants present and the grade of concrete used.
4. Deterioration in water quality resulting from potentially-contaminative activities on-Site could affect end users of groundwater abstractions. Subsurface concrete infrastructure could also be affected, depending on the contaminants present and the grade of concrete used.
5. Flooding from tidal sources and weather-induced events could affect surface waters and their suitability for use (both North Sound and mosquito control channels), through the potential mobilisation of contaminants (associated with waste material, fuel storage, etc.) on site. Flooding of surface waters could also cause detrimental effects to the Site's infrastructure, staff, and visitors, compromising the integrity of the ISWMS system and potentially risking life.
6. Flooding from tidal sources and weather-induced events could affect aquifer quality, in the event of a flood potentially causing mobilisation of contaminants which may subsequently infiltrate into the groundwater and impacting its quality.

5. Mitigation Measures

5.1 Localised flooding

A number of Potentially Significant Effects have been identified associated with localised flooding at the Site.

5.1.1 Stormwater management plan

A detailed stormwater management plan should also be prepared for the construction phase of the proposed development, which details all areas from which runoff can arise. This should also consider if or how this system interface with existing drainage systems e.g., the neighbouring GTLF The plan should then propose appropriate and adequate runoff collection and treatment options for the identified runoff, without compromising existing systems. It is recommended that, wherever possible, the principles of Sustainable Urban Drainage Systems[2] should be applied and associated pollution control measures.

5.1.2 Environmental management plan – flood risk measures

Environmental management plan (EMP) to include flood risk mitigation measures regarding minimising the risk of equipment sensitive to floodwater inundation, the siting of temporary stockpiles (or other potential sources of contamination) and measures to ensure safety of Site workers (e.g., evacuation plans).

5.2 Deterioration of water quality

A number of Potentially Significant Effects have been identified associated with deterioration of water quality for both surface water and within aquifers.

A detailed wastewater and sewerage plan should be prepared in order to minimise the risk of leaks and spills within the system. The plan should incorporate suitable treatment options for wastewater prior to discharge, in accordance with projected volumes and with the requirements of the regulatory authority.

The cap used to seal completed sections of the RWL remain effective and intact into the future, to prevent the escape of leachate or other waste material. Consideration of foreseeable changes to the local climate and sea level due to climate change must be included in the design. The RWL is intended to be constructed in a phased manner and capping of the first phase is not anticipated in the near future. Prior to any capping, additional contemporary studies should be undertaken to ensure that the current design is adequate in light of the latest climate data and modelling and procedures put in place to ensure that the ultimate construction is in line with the agreed design.

A robust strategy must be made and adhered to, preventing the disturbance of or managing existing known areas of contamination on the Site (as detailed in the Land Quality assessment). Disturbance of existing contamination is not proposed as part of the development construction or operation without a prior assessment of the contamination status of areas of potential concern and appropriate measures in place to manage risk to human health and the environment. All Site staff should have a thorough awareness of the locations of the existing contamination to reduce the likelihood of accidental disturbances or exposures.

Method statements should be prepared for all potentially-contaminative activities taking place on the Site. This must be inclusive of mitigation procedures to be used in the event of a spill or accident. It is recommended that potentially-contaminative activities are reduced where possible and take place in zoned areas whereby access to contaminant pathways and receptors are minimised as much as practicably possible. This should ideally be factored into the design and layout of the proposed development and operational management plans.

A waste management plan should be prepared inclusive of appropriate waste management for emergency situations, factoring in emergency response and flooding.

It is also recommended that groundwater is sampled and tested regularly to ensure that the abstracted water is of suitable quality for its intended use and the requirements would be documented in the environmental management plan. This would also contribute to monitoring of the groundwater to identify any potential changes in quality in response to abstraction or site operations over time.

5.3 Degradation of subsurface infrastructure

A number of Potentially Significant Effects have been identified associated with degradation of subsurface concrete infrastructure as a result of potential Sulphate or other contamination.

It is recommended that the design of the proposed development considers the use of an appropriate grade of concrete to prevent Sulphate attack in the event of groundwater contamination. It is recommended that soil and groundwater analysis is undertaken to inform a ground aggressivity assessment in order to determine a suitable design sulphate class (DS class) for the concrete structures proposed in the subsurface region.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. 5.4 Significance evaluation considering mitigation measures

The mitigation measures proposed in the subsections above have been applied to the assessment of potential hydrology and hydrogeology effects to reassess significance considering mitigation measures. Only those effects identified as “Potentially Significant” from Table 12 have been reassessed in consideration of mitigation in Table 12.

6. Conclusions

A review of the hydrology and hydrogeology indicates that the Site area is affected by extreme weather events, exposing the Site to potential tidal- and weather-related flood events, with the magnitude amplified by the low-lying nature of the Site.

Groundwater within the vicinity of the Site area is hydraulically connected to the ocean and other surface water bodies (such as the nearby mosquito control channels). This infers a tidal influence on the groundwater, and results in a considerable degree of mixing of saline water and fresher water at the transition zone, which is anticipated to be present beneath the Site. As a result, the groundwater is of high salinity and considered to be of 'low quality' and is therefore unsuitable for potable use without treatment. This is typical for groundwater on Grand Cayman, with the exception of some freshwater lenses located on the eastern side of the Island. A highly precautionary assessment of groundwater and surface water quality suggests that these waters may already be affected by contamination assumed to source from the GTLF. Based on current trends, it is anticipated that concentrations of these contaminants may increase in the near future without influence from the proposed development.

A qualitative assessment of the potential risks relating to hydrology and hydrogeology was undertaken. Based on the current proposed design (Chapter 4), a variety of potential environmental effects associated with the construction, operation and decommissioning of the ISWMS have been identified. A number of these effects have been assessed as Potentially Significant impacts.

Appropriate mitigation measures for these Potentially Significant Impacts have been recommended, many of which relate to the design of the proposed development and strategies to be adhered to throughout the construction, operation, and decommissioning phases of ISWMS.

However, it should be appreciated that, due to the current unsustainable design and practices at the GTLF and resulting impacts to groundwater quality, it is likely that the construction of the ISWMS will result in net environmental benefits in the long-term. This is due to improved waste management practices and facilities replacing the current practices at the GTLF (unlined landfill) that are currently impacting groundwater quality.

A residual significant risk relates to potential flooding occurring at the site that exceeds the criteria adopted in the site design and impacts site infrastructure.

0.0 EXECUTIVE SUMMARY

DART is advancing the design of the ReGen facility on Grand Cayman. A portion of the ReGen project requires the abstraction and injection of 11,000 gallons per minute (gpm) of cooling water. Hydrogeological desk top review and modelling (Task 1) were initiated to investigate the impacts of placing the proposed geothermal installations at the ReGen site. The aim of Task 1, as set forth in the ReGen Project, Grand Cayman - Geological and Hydrological Study and Investigation in Support of Proposed Geothermal Cooling System. Method Statement – September 6, 2021, (Method Statement) located in Appendix A was to investigate the potential impacts of the new wells relative to each other and existing groundwater users in proximity of the developments. The conclusions from Task 1 work were favorable for the continuation of Task 2 in the Method Statement.

Task 2 hydrogeologic investigation (presented herein) concludes the proposed ReGen geothermal system will be able to abstract the needed 11,000 gpm of groundwater for cooling. The injection of a like amount of heated water into the underlying bedrock formation Layer 5 (~-250 ft to ~-400 ft BGS) will have no impact on the Caribbean Sea, no impact on the residential canals or North Sound, no impact on any adjacent RO or geothermal facility considering the most-likely model scenarios **(MAX Khor – MIN Kvert),** and negligible / minimal temperature rise (0.1ºC to 0.6ºC) in abstraction zone water at the ReGen facility, in part due to migration of heated water from adjacent facilities.

1.0 INTRODUCTION

DART is advancing the design of the ReGen facility on Grand Cayman. A portion of the ReGen project requires the construction of a geothermal system consisting of abstraction and injection wells to supply and dispose of 11,000 gpm of cooling water. Investigation and analysis of the geologic and hydrogeologic aspects of the project were outlined in the Method Statement. Task 1 of the Method Statement called for a hydrogeological desk top review and use of a slightly modified existing computer model to investigate the potential impacts of placing the new wells relative to each other and existing groundwater users in proximity of the development. The

conclusions from Task 1 work were favorable for the continuation of Task 2 in the Method Statement. This report presents the findings and conclusions based on completion of those tasks.

Task 2 of the Method Statement comprised research and compilation of available data, reports, and information regarding the proposed ReGen project and nearby water users. Much of this information was provided by The Water Authority – Cayman (WAC) in its letter dated 14 July, 2020 (presented in Appendix B). This information was reviewed and relied upon for the conclusions of this report.

Task 2 of the Method Statement also consisted of the construction of an updated numerical computer model of the groundwater flow system using the most recent Modflow and MT3D code.

Finally, Task 2 of the Method Statement included this report presenting all data, calculations, model inputs/outputs, potential impacts, future development, summary and conclusions and recommendations.

Figure 1 illustrates the general setting, project location, and other pertinent details.

2.0 GEOLOGY / HYDROGEOLOGY

2.1 Geologic Framework

In addition to several historic studies, the subsurface geology of the ReGen site and in general, the western peninsula has been well documented and reported on by Dr. Brian Jones. Dr. Jones has considerable experience in investigating, analyzing and reporting on the geology of the Cayman Islands over the past 20+ years. In addition to some historical sources, five (5) of his more recent papers were reviewed for this project.

1.) Jones, B. 2013. Subsurface geology in area around the Georgetown Landfill Site, Grand Cayman. Report prepared for Apec Engineering Ltd., Grand Cayman. February 8, 2013.

2.) Jones, B., 2014. Geological attributes of the proposed Kimpton Hotel site, Grand Cayman. Report prepared for Apec Engineering Ltd., Grand Cayman. April 11, 2014

3.) Jones, B., 2020. Review of subsurface geology, central part of the western peninsula, Grand Cayman. Report prepared for Apec Engineering Ltd., Grand Cayman. May 28, 2020.

4.) Jones, B., 2020. Subsurface geology, Dart Laundry Site, Grand Cayman. Report prepared for Apec Engineering Ltd., Grand Cayman. November 24, 2020.

5.) Jones, B., 2023. Geological attributes of the Regen site, Grand Cayman. Report prepared for Apec Engineering Ltd., Grand Cayman. March 29, 2023

Jones, 2020, comments on the formations underlying the proposed ReGen site, the shallowest of which is the Ironshore followed by the Pedro Castle, the Cayman and the Brac. Regarding vertical isolation within the Cayman Formation, Jones opines: "*The uppermost Cap Rock is a very hard, finely crystalline dolostone that has porosity values of < 10% (Fig. 9). Although there is some lateral permeability, the* ***vertical permeability is very low. In contrast, the underlying Porous Unit is formed of finely crystalline dolostones that are less competent than those in the Cap Rock and have high porosities and high lateral permeabilities but low vertical permeability.***" (Emphasis added). The layers/zones used in this report as well as the material's properties and depths were delineated based on laboratory testing (Core Laboratories, Inc., Houston, Texas) of selected rock cores from the on-site test wells DUM-1, DUM-2 and DUM-3.

Previous laboratory testing of rock cores was completed for the Kimpton Test Well TW-2 and Wastewater Treatment site SHT#4 wells. The horizontal and vertical permeability and porosity data have been combined and are presented as Table 1. Note that while the permeability / porosity data for the cores from the Kimpton Test Well #2 are shown in Table 1, they were not used in calculating the maximum, average and minimum permeability values. Similar data from the SHT#4 well were used as that well is near the ReGen site. The layer boundaries are somewhat arbitrary with respect to exact depths, however, the overall permeabilities lend themselves to grouping into Layers 1, 2, 3, 4 and 5. The horizontal and vertical permeabilities for the Layer 3

cores are a good example. The designated layer boundaries do not necessarily coincide with formational boundaries as described by Jones, 2023.

Previous studies in this area and on Grand Cayman overall indicate that the formations may contain fractures that are not apparent in cores. Jones, 2023, states that:

"Assessment of the cores from wells DUM-1, DUM-2 and DUM-3, however, indicates that some fractures are present (Fig. 19B). Downhole videos of well DUM-1, which reached a depth of -406 ft, showed that fractures are common between -350 ft and -406 ft (Fig. 20). These are treated as natural fractures because it is readily apparent that they penetrate into the wall of the borehole. ***Such fractures were rarely evident in the strata above -350 ft."*** *(emphasis added).*

RCMA's review of those borehole video surveys lead to those same conclusions. The import for this project is that groundwater flow is primarily horizontal via intra formational pathways such as fissures, joint systems and solution channels.

2.2 Hydrogeology and Well Capacity

The hydrogeologic framework for the aquifer underlying the site and the entire Grand Cayman Island is based on the predominately carbonate bedrock. The groundwater flow system is located within the bedrock aquifer and exists under unconfined or water table conditions, i.e., the groundwater surface is open to the atmosphere. The flow system is also in direct contact with the Caribbean Sea and the North Sound, and the water table elevation fluctuates in response to the local tidal cycles. This has been demonstrated during several studies on the island during which pressure transducers were placed in the monitor wells. The recorded data showed the tidal fluctuations although there was some lag time between tidal periods in the ocean and those in the monitor wells. Given the saltwater nature of the surrounding water bodies, there is no permanent freshwater lens, at least in this portion of the Island.

The input for the ReGen cooling water supply is to be furnished from four (4) abstraction wells pumping at 2,750 gpm/well. Disposal of the heated water is to be accomplished using three (3)

injection (disposal) wells pumping at 3,667 gpm/well. Previous studies and operational histories of facilities such as the Kimpton/Seafire Hotel and the Hotel Indigo have shown the Cayman and Brac formations capable of meeting such demands. Verification of those conditions for this project was accomplished by conducting pumping tests using the DUM-1 (open borehole in the injection zone -250 ft to -407 ft bgl), and DUM-3 (open borehole in the abstraction zone -50 to -150 ft bgl) test wells. The abstraction (pumping) rate for each test was ~356 gpm. Water levels were monitored during each test using an electric tape and a pressure transducer was placed in DUM-1. The drawdown due to pumping stabilized relatively quickly (5 to 10 minutes), however, continued response was observed due to tidal influence. The pressure transducer in DUM-1 provided pre-test, intra-test, and post-test water level data which were then plotted against the corresponding tidal stage as shown on Graphs in Appendix C. Such tidal influences will need to be considered when planning the long-term pump settings. Analyses of the pumping test data presented in Appendix C show that the abstraction zone (DUM-3) had a specific capacity of ~213 gpm / foot of drawdown which equates to a pumping level of about -13 feet below static water level at an abstraction rate of 2,750 gpm. The injection zone (DUM-1) had a specific capacity of ~237 gpm / foot of drawdown which equates to a mounding (reverse of drawdown since this is the injection zone) of ~ +15.5 feet. RCMA advises that caution should be exercised when extrapolating a test conducted at 356 gpm to a sustainable yield of 2,750 gpm per well. Additional aquifer testing (pump testing) at a minimum rate of 1,500 gpm is warranted.

2.3 Summary of Geology and Hydrogeology

Historical studies and ongoing investigation and research in this part of the island continue to support the overall carbonate layer framework consisting of the Ironshore, Pedro Castle, Cayman, and Brac formations. In addition, the presence of the more-competent Cap Rock zone has been identified in all study areas, suggesting its regional presence, and influence on vertical flow. Although porosity and permeability of fractured carbonate rocks is generally elevated compared to other rock types, the high horizontal transmissive capacity of the Cayman and Brac formations are generally supportive of larger capacity injection and abstraction wells.

These conclusions may be absent (or short-circuited) in localized places due to micro geologic conditions, poor well construction, or lack of equipment maintenance. In review of the WAC water user table information, RCMA notes that several users are reported to have constructed boreholes/wells in which the abstraction and injection zones overlap. As such, they provide "holes / conduits" for vertical groundwater movement through the lower permeability layers. Should those conditions exist, they could lead to unforeseen consequences whereby water mixing/short-circuiting occurs.

3.0 CONCEPTUAL MODEL

Pertinent details regarding the hydrogeological conditions on Grand Cayman are presented earlier in this Hydrogeological Investigation. The conceptual model for this portion of Grand Cayman consists of features presented graphically on Figure 2.

As indicated, the proposed ReGen area occupies a portion of an island bounded on the east by a shallow sound, to the west by the Caribbean Sea, and to the north and south by adjacent areas of Grand Cayman Island, i.e., above sea level land mass. Outside of the model domain area precipitation falls on the island, some of which returns to the atmosphere through evaporation and/or transpiration. There is a small portion of the precipitation that migrates as surface water runoff into the sound and/or Caribbean Sea. A portion of the precipitation infiltrates through the fractured and porous limestone and mixes with the saltwater aquifer system.

The aquifer beneath this portion of the island consists of several zones (or layers) with varying hydraulic properties. Permeability and porosity vary within these zones both vertically and horizontally. Definition of these properties is based on work completed on this project plus several historic studies including Dr. Jones' work referenced in this report.

The geothermal system concept consists of a well (or series of wells) used to abstract groundwater, which is warmed as part of a heat-exchange process, and then injected back into the subsurface. Theoretically, the warm water injected into the subsurface will be absorbed into

the aquifer and the heat will be dissipated at a rate determined by the thermal properties of the bedrock aquifer and groundwater flow.

4.0 COMPUTER MODELING

Groundwater modeling was used in this study to describe and simulate the groundwater flow system and to simulate future heat and groundwater transport scenarios. In particular to this study, groundwater modeling was used to simulate the installation and operation of the geothermal system discussed in this report. RCMA utilized the USGS Modflow Code to simulate the groundwater flow portion of the simulation and MT3D to simulate the heat transport.

The following tasks were completed with respect to groundwater modeling for this study:

- Review of existing hydrogeological data and geothermal system data;
- Development of a conceptual model for the area and conversion of the conceptual model into model code (working simulation);
- Adjustments to the model based on published empirical and site-specific hydrogeological parameters and calibration to the existing hydrogeological conditions;
- Injection/abstraction of groundwater based on a variety of potential geothermal system configurations; and,
- Various sensitivity analyses.

Further details are presented below.

4.1 Model Description

4.1.1 Computer Code

RCMA utilized the USGS model code MODFLOW to simulate groundwater flow in this study.

MODFLOW is the industry-standard model used to simulate groundwater flow in three dimensions. This code has been used to construct thousands of simulations since it was first introduced in 1984. MODFLOW was also used by Bender (2004) in its simulation of the West Indian Club Geothermal Feasibility Study and by RCMA in the Kimpton/Seafire (KGC) study (2014) and the Hotel Indigo study (2022).

The MODFLOW code simulates groundwater flow by solving the groundwater flow equation at each cell, assuming that flow is homogeneous and isotropic within that cell. In this way, it is possible to simulate groundwater flow in porous media. Discussion earlier in this report indicated that although the aquifer materials are carbonates (usually associated with fracture flow) the materials are porous enough and have a high enough degree of secondary/dual porosity to behave like standard porous media. This makes the use of the MODFLOW code valid.

Model code MT3D was used for the heat transport portion of the simulations. MT3D was developed to simulate contaminant movement in groundwater (solute transport), however, the heat transport and the solute transport equations are analogous. MT3D is routinely used for heat transport in groundwater systems by substituting thermal properties for the solute transport properties commonly input. In these simulations, temperature was input as "concentration" and thermal dispersivity for "hydraulic" dispersivity.

4.1.2 Model Construction

The MODFLOW flow model was constructed once the conceptual model was developed and reviewed. RCMA utilized Groundwater Vistas, a pre- and post-processing software package to assist in the development of the model and its population with data variables.

The modeled area is illustrated on Figure 3 and consists of 128 rows, 108 columns and 5 layers (~69,000 cells). Finite difference models use rectilinear cells to overlay the simulated area. These square and rectangular cells are placed over the area to be simulated and the groundwater flow equation is solved for the center of each cell. Cell sizes and shapes are refined to reach a balance

between an appropriate number of cells for the simulation and a simulation that is not overly cumbersome to solve.

The edges of the model domain are represented by constant head cells which represent the water level and temperature of the Caribbean Sea (ocean) as it surrounds the island. Care is generally exercised in the use of constant head cells; however, the ocean is perhaps the finest example of a "constant head" found in nature. Therefore, RCMA believes its use in this simulation is appropriate. Cells outside of the constant head cells are represented by no-flow cells and no simulation is completed in these areas.

Input parameters were based on data from published and unpublished documents/reports, drilling logs from three (3) test wells (DUM-1, DUM-2 and DUM-3), review of borehole video surveys, information from Dr. Jones assessment of the geology/lithology; and laboratory testing of the permeabilities, porosity and thermal conductivity of rock cores from selected subsurface layers. These are further described below.

4.1.3 Layers and Other Properties

The layers were assigned and developed based primarily on the hydrogeological information, predominantly vertical and horizontal permeabilities discussed in this report. The layer elevations and thicknesses are illustrated on Table 1 and generally represent the different facies described by Jones 2014, 2022, 2023. Hydraulic and other properties assigned to these layers and the cells within each layer are also presented in Table 2 and are described below. These "base values" were used at the start of the model simulations and were subsequently varied and/or refined as the simulations were refined.

Model inputs consist of various parameters such as: permeabilities, storage, porosity, recharge, temperature, thermal conductivity, and dispersivity. Model input parameters were determined based on field collected data within the study area, regional observations, and empirical published values. In the end, ranges of these properties were utilized to calibrate the model to the quasi-equilibrium status of the system and all were subjected to sensitivity analyses.

Permeability

The permeability (K) values of the model were varied within the ranges presented in Tables 1 and 2. The layers/zones as well as the material's properties and depths were delineated based on laboratory testing of selected rock cores from the on-site test wells DUM-1, DUM-2 and DUM3 in combination with historic results. This current testing was performed by Core Laboratories of Houston, Texas who have also conducted similar tests on test well cores from the Kimpton/Seafire and Indigo Hotel projects. Historic values of permeability were based on testing performed by Jones, 2014 as well as field testing performed by APEC personnel and calculations performed by RCMA, 2014, in the Kimpton/Seafire (KGC) report.

Values of permeability had a significant effect on the model output. Additional discussion is presented in the sensitivity analyses section below.

Storage

Values of storage and effective porosity were varied based on available published information. Values of porosity used in scenarios ranged from 7 % to 25% and were based on core testing reported by Jones, 2014, 2023. Values of storativity were based on empirical values and were varied from $5x10^{-3}$ to $5x10^{-5}$. Varying the values of storativity did not have significant effects on the model output.

Recharge

Recharge is that component of the hydrogeologic cycle that actually enters the groundwater flow system. Recharge rates for the Caribbean islands vary greatly from season to season depending on climatic factors and also tropical storms and hurricanes. A value of eight (8) inches per year was used in the simulations. Varying the recharge rate did not have significant effect on the simulations unless an abnormally high (i.e., greater than the actual rate of precipitation) value was used.

Dispersivity

Dispersivity is a measure of the amount of solute mixing (heat in this study) in groundwater and is composed of two terms; dispersion and diffusion. Attempts have been made in the lab and field to quantify values of this parameter for various locations and hydraulic materials, but generally, its value is determined during the modeling process. Values between 0.3 ft and 30 ft were used in the scenarios. Varying values of dispersivity did not have a significant effect on the model.

Constant Head and Heat Source Temperature

The simulations utilized heat concentrations of the Caribbean Sea and the North Sound areas coupled with constant water surface elevations along these margins. The constant elevation heads were maintained to simulate average elevations of the water (approximately mean sea level). In the Kimpton/Seafire (KGC) model, 2014, groundwater temperatures at depth were based on borehole fluid temperature log of TW#1 performed by Mundell, 2014 and varied from approximately 28.5°C (83.3°F) at a depth of 50 ft BGS to 28.0°C (82.4°F) at 150 ft BGS. The temperature in TW#2 at 380 ft BGS was about 27.7°C (81.9°F). The Indigo Hotel model, 2022, used these temperatures as a basis and incorporated some site-specific measurements from that project site.

At the ReGen project site, temperature surveys were completed on test wells DUM-1, DUM-2 and DUM-3 from the water's surface to the borehole bottom: DUM-1 was surveyed on 30 November 2022 to a depth of ~ -251 ft and again on 12 April, 2023 to a depth of -412 ft; DUM-2 was surveyed on 12 December 2022 to a bottom hole depth of -207 ft; and, DUM-3 was surveyed on 12 April, 2023 to a bottom hole depth of ~ -141 ft. The results have been used to assign the groundwater temperatures at the tops and bottoms of each layer used in the computer modeling as presented Table 2. Bottom hole temperature in DUM-3, which represents the abstraction zone, was 81.15ºF although DUM-1 and DUM-2 had temperatures of 80.38ºF and 80.76ºF at -150 ft, respectively. The bottom hole temperature in DUM-1 at -412 ft (injection zone) was 76.08ºF. These available temperature data indicate that the initial temperature values used in the Kimpton/Seafire (KGC) and Indigo Hotel models were valid and remain within expected ranges.

Furthermore, these data suggest that the hydraulic separation provided by the lower permeability materials exists, at least on a regional scale in this part of the island.

As described by Jones,2014, 2022 and 2023, solution channels and fractures in these materials may exist locally in this part of the island. Such conditions have been confirmed through the examination of bedrock cores and borehole video surveys. While they exist, the degree of interconnectivity both horizontally and vertically is unknown. The borehole video surveys show these solution channels and fractures to have limited vertical extent. Jones, 2023, states: "*Assessment of the cores from wells DUM-1, DUM-2 and DUM-3, however, indicates that some fractures are present (Fig. 19B). Downhole videos of well DUM-1, which reached a depth of 406 ft, showed that fractures are common between 350 and 406 ft (Fig. 20). These are treated as natural fractures because it is readily apparent that they penetrate into the wall of the borehole.* ***Such fractures were rarely evident in the strata above 350 ft." (emphasis added).***

These data provide empirical support for the simulations incorporating the minimum vertical permeabilities of these materials as being more representative of actual bedrock characteristics than those considering higher vertical permeabilities.

<u>Thermal Conductivity</u>

Thermal conductivity was determined through testing completed by Core Labs, 2023, and their report shows a thermal conductivity value of 1.089 Btu/hr-ft-F for a sample from ~118-128 ft BGS, a value of 0.918 Btu/hr-ft-F for a sample from ~145-155 ft and a value of 1.125 Btu/hr-ft-F for a sample from ~160-170 ft BGS. RCMA coupled these values with values on tests completed by Core Lab, 2014, for the Kimpton/Seafire project as follows: a thermal conductivity value of 1.24 Btu/hr-ft-F for a sample from ~151 ft BGS and a value of 1.024 Btu/hr-ft-F for a sample from ~240 ft BGS. These values of thermal conductivity are in line with published values for limestone/dolostone.

The model can be made sensitive to this parameter, but only when it was varied outside of the range of expected actual values. This outside the range response is similar to variances in the recharge input and abnormally high values of thermal conductivity.

Water Input and Extraction - ReGen

The geothermal system demands for the ReGen were provided by APEC and incorporated into the project are as follows:

- The ReGen total demand of 11,000 gallons per minute (gpm). Four (4) abstraction wells pumping at 2,750 gpm/well and three (3) injection (disposal) wells pumping at 3,667 gpm/well.

A long-term temperature differential (ΔT) of +18°F (+10.08°C) was provided and used in the Task 1 modeling as discussed in the preliminary modeling report. Additionally, an intermittent temperature rise of +22°F (+12.22°C) for up to four (4) month intervals was also reviewed and modeled in the Task 1 work. A base groundwater temperature of 82.94°F (28.3°C) was used in the modeling. Two simulations were run – one considering Max Khor and Min Kvert and the other considering the Max Khor and Ave Kvert The Min Kvert allowed less vertical expansion of heated water and so the temperature in Layer 2 (the abstraction layer) rose by ~0.2-0.4°C after 4 months.

All final simulations of the model assumed abstraction from wells in Layer 2 (open borehole from ~-51ft to ~-149ft BGS) and injection into wells in Layer 5 (open borehole from ~-270ft to ~-400ft BGS).

Water Input and Extraction - Other Users

The WAC, 2020, provided a figure, list, and summary description of major water users in its letter and suggested that consideration be given to such users in future modeling efforts. As illustrated on the WAC figure and table, there are a number of major water users in this portion of the island. Planned or future systems were not considered in these simulations.

RCMA utilized this information to input these water users into the model. This information is provided in Table 3. As appropriate, RCMA summarized and simplified this information. In all cases however, the following data were not changed from the WAC information: general location of the water user; total volume/rate of water abstracted or injected; approximate depth/zone of abstraction and/or injection; temperature of heated water (as applicable to some systems). For a more-efficient model, RCMA combined wells/locations/flow rates on a specific property; estimated the locations of wells on a particular parcel; and generalized pumping periods. An example of this simplification is seen at the User 3 facility in the WAC letter. That facility consists of eight abstraction wells removing a total of ~5,000 GPM of water from the 100-150 ft BGS interval and three injection wells inputting a total of ~3,350 GPM of water into the 200-250 ft BGS interval. According to WAC, these wells do not all operate continuously – rather operating based on need, maintenance, and repair schedule. Rather than consider many different potential pumping cycles/scenarios, RCMA chose to model the system with one injection well and one abstraction well as follows: one injection well injecting ~3,350 GPM of water into Layer 5 and one abstraction well removing ~5,000 GPM from Layer 2 which equaled the total "in" and total "out" for that system. These adjustments allowed the model simulations to be constructed and run in a more efficient manner.

4.2 Sensitivity Analyses

The previous section presented the hydraulic and other properties that are input to the model. Each of these variables is important to the overall representation of the hydrogeologic system. In addition, each variable has the potential to affect the results of the model. For this reason, the inputs are varied in order to determine which item(s) has/have the potential to significantly affect the output. The model is said to be "sensitive" to these input variables. A general practice of variance is to adjust each property by an order of magnitude (up and down) and observe the effects on the model output.

Some properties cannot be varied much due to the absolute/exact value required for the simulation. A good example of this type of variable in this project would be the

abstraction/injection rates. Changing these rates would likely have a great effect on the model output, however, these pumping rates are known and must be present at the determined rate, otherwise the systems would not work as designed. These properties are generally not varied in a sensitivity analysis.

Other properties can be varied, but significant variability is not possible in a natural system. Recharge is a good example of this type of property. Increasing the recharge rate from 10 inches per year to 100 inches per year would be a standard part of a sensitivity analysis, however, 100 inches of recharge per year far exceeds the precipitation for the area. These types of properties are generally varied a realistic amount depending on the specific property and conditions/location of the model.

Finally, some properties can exist in certain areas at values that span several orders of magnitude. Permeability is one of these parameters. The testing of bedrock cores from the project area has documented values of permeability ranging from less than 1 ft/day to >10,000 ft/day. These properties are varied within (and slightly outside) of that range to determine sensitivity.

Results of modeling for this project indicated that the model appears most sensitive to the ratio of horizontal and vertical permeabilities. Further discussion of this is presented in the modeling results section below.

4.3 Model Input/Output

Several model runs were simulated once the parameter values were collected and established. Several dozen runs were completed to establish selected parameter values and determine preliminary sensitivity analyses. Once complete, the final modeling consisted of 4 separate simulations:

- Average horizontal and vertical hydraulic conductivity **(AVG Khor – AVG Kvert)** – a simulation used to represent “average” hydraulic conditions measured at the property

coupled with regional understandings (The output from these model runs is considered possible of actual conditions).

- Minimum horizontal and vertical permeability **(MIN Khor – MIN Kvert)** – a simulation used to represent conditions of low horizontal and low vertical flow. Although the framework for these simulations provides the lowest vertical permeability (and therefore the lowest chance of heated water migration through the layers) the minimum horizontal permeability does not appear to represent regional values. The output from these model runs is considered best case for vertical protection but not likely due to the limited amount of injected water available for cooling.

- Maximum horizontal and vertical permeability **(MAX Khor – MAX Kvert)** – a simulation used to represent significant vertical and horizontal flow. This is not a likely condition, but this simulation is used to represent a worst-case hydraulic scenario. Similar to the MIN Khor – MIN Kvert scenarios above, the higher values of vertical permeability do not appear to accurately represent the actual measured conditions of the formations described by Jones and measured in the studies noted in this report.

- Maximum horizontal and minimum vertical permeability **(MAX Khor – MIN Kvert)** – a simulation representing high horizontal flow coupled with low potential for vertical flow. This would represent the best-case scenario and, based on collected data, these conditions appear most likely even on a regional scale.

In reality, the most likely case of permeability would consider the potential for higher horizontal flow in certain areas, but average horizontal flow in most areas. This would be coupled with low vertical flow potential where short circuiting or cross-layer open boreholes are not present.

The existence of this condition is supported by the core testing data and visual inspections presented by Jones, 2014,2022, 2023 and hydrograph discussions in RCMA-KGC, 2014, borehole

temperature surveys of KIM-TW-2, the out-of-service Kimpton/Seafire abstraction well and test wells IND-TW-1 and IND-TW-2, and DUM-1, DUM-2, and DUM-3, the operational experience at the ACWW and Kimpton/Seafire facilities.

Each of these simulations was tested using the pumping rates noted above.

4.4 Model Output Results

Simulations were run to establish a steady-state flow solution for each model. Once this was complete, a transport simulation was run for each model simulation for periods of 1, 5, and 10 years as requested by the WAC. RCMA noted that a quasi-equilibrium of the temperature readings was often reached after between 5 and 10 years of operation, meaning that the rate of increase in the temperature approached zero at this point.

Results of the increase in groundwater temperature (if present) and model discussion are presented on Table 4 and on Figures 5A, 5B, 6A, 6B, 7A, 7B, 8A, and 8B.

The figures all utilize a similar data presentation. Graphical "color floods" of water temperature are superimposed over the model grid in plan view illustrating the results of the 1- 5- and 10-year simulation times. Dark blue/purple colors are colder (25+°C) green is moderate (32°C) and yellow is warm (greater than 38°C). A cross section of each simulation is presented above the plan view and is centered on the ReGen abstraction wells.

Additional discussion is presented for each of the simulations noted below.

- Average horizontal and vertical permeability (**AVG Khor – AVG Kvert**) – (Figures 5A and 5B)

  These simulations illustrate a rise of up to 0.3°C at the DART Laundry facility and a rise of up to 3.3°C in the groundwater at the ReGen plant. This rise in temperature appears to be caused by migration of heated water from Layer 1 and Layer 5 and injection of warm water by the Government Administration Building and other users into Layer 2 of the model. Other nearby

users do not appear affected by the ReGen injection of the warm water into Layer 5. These temperature increases are among the highest observed in these simulations and illustrate the effect that a moderate horizontal K coupled with a moderate vertical K could have on the movement of groundwater and heat.

The output from these model runs is considered **Worst Case and Not Likely**.

- Minimum horizontal and vertical permeability **(MIN Khor – MIN Kvert)** – (Figures 6A and 6B)

These simulations illustrate no rise in temperature at the DART Laundry facility and a rise of up to 1.0°C in the groundwater at the ReGen plant. This rise in temperature appears to be caused by migration of heated water from Layer 5 and injection of warm water from other geothermal system users into Layer 2 of the model. It should be noted that this simulation causes areas of Layer 1 to "dry" due to the pumping of the Regen wells. As noted earlier in this report, the formation hydraulic conditions do not support this. Rather, the findings of this study indicate there is ample water available for the planned pumping.

The output from these model runs is considered **a Good Case but Unlikely**.

- Maximum horizontal and vertical permeability **(MAX Khor – MAX Kvert)**- (Figures 7A and 7B)

These simulations illustrate essentially no temperature rise at the DART Laundry facility and a rise of up to 2.6°C in the groundwater at the ReGen plant. This rise in temperature appears to be caused by migration of heated water from Layer 1 and Layer 5 and injection of warm water by the Government Administration Building and other users into Layer 2 of the model. Other nearby users do not appear affected by the ReGen injection of the warm water into Layer 5. These temperature increases are among the highest observed in these simulations

and illustrate the effect that a high horizontal K coupled with a high vertical K could have on the movement of groundwater and heat.

The output from these model runs is considered **Worst Case and Not Likely**.

- Maximum horizontal and minimum vertical permeability **(MAX Khor – MIN Kvert)** – (Figures 8A and 8B)

These simulations illustrate essentially no temperature rise at the DART Laundry facility and small rises of 0.1°C after 1 year, 0.3°C after 5 years and 0.6°C after 10 years in the abstracted groundwater at the Regen plant. This rise in temperature appears to be, at least, partly caused by injection of warm water from other geothermal system users into Layer 2 of the model. Other nearby users do not appear affected by the Regen injection of the warm water into Layer 5. The output from these model runs is considered **Most Likely in Localized Areas and Possibly Regionally**.

5.0 DISCUSSION

5.1 Sustainable Yield

Results of the model simulations indicate that the aquifer system is capable of providing the 11,000-GPM input to the ReGen geothermal system.

The areally- and vertically extensive aquifer will be able to provide the required abstraction with minimal drawdown as evidenced by the operations at nearby systems and pumping tests already completed (See Section 2.0). The abstracted volume will be recharged via horizontal groundwater flow from the ocean, periodic discharge from storm water drains into the abstraction zone and areal recharge (precipitation) to the system.

The injection of warm water into the deeper aquifer (injection zone) is another point to consider in the sustainability of the system. As indicated, the simulations indicate that a quasi-equilibrium

condition will form in the aquifer system whereby the heat added by the injected warm water will be dissipated into the system.

These items considered, the volume of water required and the adjustment to the aquifer system by the warm water injection is a sustainable use of this resource.

5.2 Impact on the Environment

Testing performed during this study and the simulations discussed above show that minimal, if any, impact to the environment will occur due to this system. In particular:

- Limited drawdown of the groundwater levels will occur when the system is in operation;
- Limited warming of the groundwater in the abstraction zone (model Layer 2), principally beneath the property will occur due to the operation of this system, i.e., low vertical permeability and injection into Layer 5 (~-270 and ~-400 ft BGS); and
- None of the injected warm water from the ReGen facility will reach the Caribbean Sea, North Sound, the residential canals or nearby water users based on in situ conditions being similar to the MAX K hor and MIN Kvert permeabilities and other inputs to the model.

5.3 Potential for Short Circuiting

There are two (2) forms of short circuiting that need to be considered. The first is vertical migration from the injection zone Layer 5 (~-270 – ~-400 ft BGS) upward into the abstraction zone Layer 2 (~-51 – ~-149 ft BGS) via joint and fracture systems, i.e., high vertical permeabilities. Previous studies in this area and on Grand Cayman overall indicate that the formations may contain fractures that are not apparent in cores. Jones, 2023, states: *"Assessment of the cores from wells DUM-1, DUM-2 and DUM-3, however, indicates that some fractures are present (Fig. 19B). Downhole videos of well DUM-1, which reached a depth of -406 ft, showed that fractures are common between -350 ft and -406 ft (Fig. 20). These are treated as natural fractures because*

it is readily apparent that they penetrate into the wall of the borehole. ***Such fractures were rarely evident in the strata above -350 ft. "*** *(emphasis added).*

RCMA's review of those borehole video surveys lead to those same conclusions. The import for this project is that groundwater flow is primarily horizontal via intra formational pathways such as fractures, fissures and solution channels. Empirical support for minimal vertical hydraulic communication between these zones comes from the operation of the Abel Costello Water Works (ACWW) facility, the hydrographs in RCMA, 2014, and temperature measurements completed in the noted studies. The ACWW withdraws approximately 5,000 gpm from wells with open boreholes between 100 – 150 ft BGS which is the equivalent to Layer 2 in this study. It then injects about 3,350 GPM of high salinity brine (RO effluent) into a zone between 200 – 250 ft BGS. Both the abstraction and injection wells are located on facility property in relatively close proximity. The continued operation of the ACWW indicates that the vertical permeability of the 150 – 200 ft BGS layer is sufficiently low to prevent short circuiting. Empirical Information for the Kimpton/Seafire site also indicates that a low permeability zone exists between Layer 2 and the deeper layers. See discussion in Section 4.1.3 – Layers and Other Properties above. As shown in RCMA, 2014, the hydrographs for TW#1 and TW#2, as presented in Graph 4 of that report show that the water level in TW#1 is consistently higher than in TW#2. TW#1 is open borehole from 50 – 150 ft BGS whereas TW#2 is open borehole from 50 – 380 ft BGS. Were there good hydraulic communication between the 50 – 150 ft zone and the deeper formation the water levels would be expected to be in close agreement. The deeper flow zone in TW#2 appears to control the head. Note the hydrographs for TW#2 and Lobster Pot (Caribbean Sea) are almost identical.

The second form of short circuiting relates to well construction, particularly that of the injection wells. Care must be taken to assure that the grout seal in the annulus between the well casing and the surrounding rock is continuous. Proper grouting will preclude the potential for vertical migration via the annulus.

It should be noted that several of the wells/well systems identified by WAC have boreholes that are open to several of the formations (Cayman and Brac). These have been used in the modeling as presented. The model simulations illustrate that these structures are providing pathways for such short circuiting to occur. Future use of such WAC information should be field verified.

6.0 CONCLUSIONS

1. Pumping tests DUM-1 and DUM-3 demonstrated that the ReGen system demand of 11,000 GPM, (2,750 GPM per well), can be met with four abstraction wells. The abstraction zone is Layer 2 (~-51ft to ~-149ft BGS).

2. The discharge from the system can be injected via three injection wells at the northwestern portion of the site at a rate of 3,667 GPM each. The injection zone is Layer 5 (~-270 to ~-400 BGS. The design criteria are 2,750 GPM abstraction and 3,667 GPM injection with injected water at a delta-temperature of +10.08°C.

3. Computer modeling of the proposed abstraction/injection well design and layout demonstrates:

- No impact on the Caribbean Sea due to the ReGen system;
- No impact on the residential canals or North Sound due to the ReGen system; and,
- No impact on any adjacent RO or Geothermal facility due to the ReGen system, considering the most-likely model scenarios **(MAX Khor – MIN Kvert).**
- Negligible / minimal temperature rise (0.1°C to 0.6°C) in abstraction zone water at the ReGen facility in part due to migration of heated water from adjacent geothermal facilities considering the most-likely model scenarios **(MAX Khor – MIN Kvert).**

7.0 LIMITATIONS

The groundwater user information provided in the WAC, 2020, spreadsheet was relied upon for the modeling conducted as part of this project. Modeling suggests that groundwater temperature changes may be occurring within the various formations at some locations in this part of the island. Some of these temperature changes are potentially due to injection/abstraction well boreholes being open over several depth/layer intervals and other changes appear due to the layer utilized for abstraction/injection. These changes should be confirmed/validated through additional data gathering, verification and modeling.

APPENDIX A

ReGen Project, Grand Cayman - Geological and Hydrological Study and Investigation in Support of Proposed Geothermal Cooling System.
Method Statement – September 28, 2021

September 28, 2021

ReGen Project, GRAND CAYMAN
GEOLOGICAL AND HYDROLOGICAL STUDY & INVESTIGATION IN SUPPORT OF PROPOSED GEOTHERMAL COOLING SYSTEM

METHOD STATEMENT

1.0 BACKGROUND AND INTRODUCTION

ReGen is advancing the design of an energy recovery facility (ERF) at 11B91&94, George Town, Grand Cayman. A dedicated geothermal cooling system is proposed to service the new development. The average flow required for the cooling system is estimated to be 11,000 gallons per minute (gpm) with a temperature delta of 18 Fahrenheit. The values of the cooling water flow demand and temperature differential are the expected values for the lifetime of the project and are based on the ERF functioning at full thermal capacity.

The preliminary proposed locations of the ERF geothermal cooling wells will be developed using the following general criteria.

- Provide a minimum of four (4) abstraction wells and three (3) disposal wells.
- Minimum horizontal separation of 100ft between abstraction wells and 200ft between disposal wells. This is the proposed horizontal separation between the wells within the abstraction and disposal groups. In other words, the abstraction wells will be located at a minimum spacing of 100ft to next abstraction well.
- Minimum horizontal separation of 2,000ft between the nearest disposal and the nearest abstraction well.

Geothermal systems on Grand Cayman are typically based on the abstraction of cooler deeper groundwater and the disposal of the same but heated water at a shallower elevation (this model can be reversed so that the heated water is discharged at the deeper elevation). The actual depths of abstraction and disposal wells will be confirmed based on the hydrology study findings. The presence of an aquitard (*Cap Rock*) between the disposal point and the abstraction point greatly reduces the risk of a short circuit where the warmed water is taken back into the geothermal system.

The nearby North Sound and the presence of other ground water users in proximity to the proposed geothermal system needs to be considered. The disposal of the warmed ground water may impact the North Sound and the operations of neighbouring groundwater users. Hydraulic modeling and pilot wells are used to analyze and quantify the risk of impacts. The modeling can also be used to mitigate predicted impacts. The study and the hydrological model will also address potential impact on the North Sound and the Caribbean Sea.

The tasks to be undertaken are set out in the following table and narrative sections. They are intended to meet ReGen's brief and be responsive to the requirements for further hydrogeological studies articulated in the Terms of Reference of the Environmental Impact Assessment of the ReGen project. This study will be integrated in the EIA to apply for a groundwater abstraction license and discharge permit as required by the Water Authority Act.

Task #	Title	Task Description
1	**Initial desktop and modelling review prior to hydrogeological field investigation and detailed modeling for proposed geothermal installation for ReGen ERF Waste Heat Disposal**	This review will investigate the geothermal impacts of the proposed installation to service the proposed ERF. A hydrological model will be developed using information from our previous work and groundwater user information provided by the Water Authority (WAC). Predicted geological profiles based on a compilation of our historic investigations in this part of the George Town district will be modelled. The modeling will investigate the impacts of the new wells on each other and existing installations using the ground water aquifer. The well locations and design will be adjusted to mitigate their impacts and to optimize their performance for the proposed installation to service the ERF. This desktop study will be presented to ReGen and EAB/WAC for their review prior to commencement of the proposed pilot wells and detailed study report as set out in Task 2.
2	**Hydrogeological in field investigation, testing and modeling for the proposed geothermal installation for the ERF. Draft and final reports for client and environmental review board (EAB) review**	Study including placing pilot boreholes and field and laboratory testing followed by permitting support services as described in this method statement. The pilot bores can be converted to monitoring or production wells. The findings and conclusions of this investigation, testing and modeling study will take precedence over the predictions of Task 1. The draft and final reports will be presented to ReGen and EAB/WAC for their review and commentary.

1.1 TASK 1

Develop a hydrological model for the site to include neighbouring groundwater users. The model will be used to predict, subject to the future findings from geological borings and laboratory testing of rock cores, the outcome of the following scenarios.

1. Impacts on groundwater of operating the proposed 11,000 gpm / delta 18° Fahrenheit geothermal cooling system to service the proposed ERF at 11B91&94.

2. Proposed mitigation measures to help counter any predicted negative impacts from the proposed geothermal cooling system on existing neighbouring ground water user operations. Task 1 will provide an estimate of anticipated zone of temperature variance. This will provide a preliminary indication of the impact of discharged water on adjacent groundwater users.

The report on the Task 1 predictive study will be submitted to the Environmental Advisory Board (EAB) for review and commentary. It is understood that the WAC is a member of the EAB.

1.2 TASK 2

Task 2 covers the field investigation using pilot test boreholes to determine the rock profile with depth, its characteristics including porosity, water flow paths and potential volumes. Rock chippings and cores are taken for visual review and laboratory analysis to determine densities, porosities, fracture characteristics and thermal conductivity. Pumping tests are carried out. The field results are incorporated into the hydrological model to determine the optimum location and design of the wells and to mitigate their impacts on surrounding ground water users. Final reports on the hydrogeological study and recommendations for appropriate well placement and design are provided. Seeking direction and discussing the report with the authorities is included in Task 2 activities.

For the purposes of this proposal, it has been assumed that two boreholes to a depth of 400ft and 150ft below grade will be sufficiently deep to provide a profile of the rock formation including a clear definition of the location and thickness of the *Cap Rock*. If field investigations indicate otherwise, the location and depth of the boreholes may have to be altered.

2.0 DETAILED SCOPE OF TASKS

TASK 1

Review all available reports, documents, literature and data pertaining to geologic/hydrogeologic conditions in the area and existing reverse osmosis (RO) and geothermal cooling systems.

Meet with WAC personnel as well as others to discuss the proposed systems, determine regulatory requirements, and operational history of their existing facilities.

A hydrological model based on information from our previous work and groundwater user information provided by the Water Authority (WAC) will be further informed by predicted geological profiles based on a compilation of our historic investigations in this part of the George Town district.

The modeling will investigate the impacts of the new wells on each other and existing installations using the ground water aquifer. The proposed well locations and design will be adjusted to mitigate their impacts and to optimize their performance for the proposed installation.

This desktop study will be presented to ReGen and EAB/WAC for their initial review prior to advancing the final study reports on completion of Task 2.

TASK 2

The field geological investigation will identify the underlying rock formations and the physical characteristics and condition of these formations. A suite of laboratory tests will be conducted on rock cores to determine the porosity and vertical and horizontal permeabilities of the rock.

The investigation will include:

1. Drilling, coring and logging a six (6)-inch diameter borehole (BH#1) to 400 feet below ground level approximately. Borehole may be located so that it can be later reamed out to a larger diameter and used as a monitoring well for the proposed geothermal system. APEC will record the penetration rate and the pull-down pressure on the drill-bit every five feet and/or change in formation. Ten (10), ten foot long cores and drill cuttings will be obtained during the first 250 feet of drilling followed by taking drill cuttings every five-feet and/or change in formation for the remaining 150 feet of drilling. Some additional cores may be taken below the 250 feet mark. Fifteen samples from these cores will be selected and sent to our geologist for whole core porosity and permeability testing amongst others including thermal conductivity. A borehole video camera and temperature/conductivity probe will be run the entire length of the 6-inch diameter, 400ft deep pilot borehole. The data obtained will be used to correlate/confirm the lithology, apparent porosity and

permeability and to determine the ambient vertical groundwater temperature gradient.

Please note that it is very important to assess the presence/thickness/or absence of the *Cap Rock* or some other low permeability layer that can act as a hydraulic barrier (aquitard) between the abstraction and injection zones. The number and depth of core samples to be taken as well as the number of core samples to be tested are provided as an estimate based on similar previous work. The actual number of cores as well as the number of core samples to be tested will be adjusted depending on test well drilling information in real time.

2. Collect groundwater sample(s) and analyze for chemical composition as needed for the geothermal system. Contact equipment manufacturer/supplier for water quality specifications.

3. The elevation of the measuring point for the borehole will be surveyed and a pressure transducer installed and monitored to determine any tidal fluctuations.

4. Drilling a six (6)-inch diameter test well (BH #2) to the bottom of the *Cap Rock* at the location selected based on the preliminary hydrological model. Again, it is very important to verify the presence and thickness of the *Cap Rock*. Five (5) ten feet long cores and well cuttings will be obtained from this well. Five samples from these cores will be selected and sent to the geologist for whole core porosity and permeability testing amongst others including thermal conductivity at the selected location along the depth of the borehole to the bottom of cap rock. Drilling protocols, temperature logging and borehole video survey will be conducted in the same manner as for BH #1. The open borehole will be grouted back to the top of the *Cap Rock*, with surface casing installed as needed. The elevation of the measuring point will be surveyed and a pressure transducer installed. Monitoring of the pressure transducers in BH #1 and BH#2 will be carried out for a minimum of 48 hours to see if there are any head differentials between the shallow and deep wells to demonstrate hydraulic separation. Water level measurements will be made in both BH #1 and BH #2 at six hour intervals with an electric tape. Also use lag times to calculate aquifer transmissivities.

   The number and depth of core samples to be taken as well as the number of core samples to be tested are provided as an estimate based on similar previous work. The actual number of cores as well as the number of core samples to be tested will be adjusted depending on test well drilling information in real time.

5. A data logger will be installed at the North Sound. Tidal data from the data logger will assist in calibration of the hydrology models.

The hydrological modelling work will include:

- Constructing a model of the groundwater flow system using the latest version of MODFLOW and MT3D. The MODFLOW code simulates groundwater flow by solving the groundwater flow equation at each cell, assuming that flow is homogeneous and isotropic within that cell. In this way, it is possible to simulate groundwater flow in porous media. Although the aquifer materials are carbonates (usually associated with fracture flow) the materials are porous enough, fractured enough, and have a higher enough degree of secondary/dual porosity to behave like standard porous media. This makes the use of the MODFLOW code valid. Model code MT3D is used for the heat transport portion of the simulations. MT3D was developed to simulate contaminant movement in groundwater (solute transport), however, the heat transport and the solute transport equations are analogous. MT3D is routinely used for heat transport in groundwater systems by substituting thermal properties for the solute transport properties commonly input. In these simulations, temperature was input as “concentration” and thermal dispersivity for “hydraulic” dispersivity.

- This approach will be presented to the WAC at the preliminary meeting for consensus. Input parameters would be based on data from published documents/reports, the geological assessment of the subsurface lithology, thermal conductivity of the *Cap Rock*, porosity and permeability testing, the borehole video log, lag time calculations, head differential and others. The model will be calibrated to actual head conditions.

- Query model for:
    - Locations/spacing of four (4) 400ft deep abstraction wells each pumping at 2,750 gpm (+/) and three (3) 150ft shallow injection wells each injecting at 3,700 (+/-) gpm.
    - Incorporate the locations, depths and abstraction/injection rates for identified RO and geothermal systems in the area.
    - Determine the extent and magnitude of thermal impacts on the groundwater flow system, existing RO and geothermal systems, North Sound and other surface water bodies.

Finally, a draft and final report will be presented. These will capture the geological, borehole surveys/logs and hydrological investigation, hydraulic modeling results, presenting all data, calculations, model inputs/outputs, potential impacts and recommendations on the feasibility of the proposed geothermal system from a geological and hydro-geological perspective.

3.0 APEC'S TEAM

The APEC team comprises the following.

- **Dr Brian Jones, Geologist**
  Dr Jones is WAC's preferred geologist. He is the preeminent expert in the geology of the Cayman Islands. Brian was the geologist for the Kimpton Seafire geothermal system and many other projects in the Cayman Islands.

- **Mr Robert Minning, Hydrologist, R.C. Minning and Associates, Inc**
  Bob Minning is the hydrologist for the Kimpton Seafire geothermal system and Dragon Bay and Dart Central Laundry RO projects.

- **Mr Pearse Murphy, Mr Ali Sabti, Mr Denis Murphy, Mr Daniel McCarthy, Mr Adam Cullen, APEC Consulting Engineers Ltd**
  APEC carries out project lead and scoping tasks and is very familiar with Cayman's geotechnical and deep well construction practices. APEC provides project performance specifications for contractors, logistics, field samples and data collection, fieldwork supervision of the Kimpton Seafire, Central Laundry and other investigations, liaised with the authorities and carried out permitting tasks for the award of the requisite licenses.

APPENDIX B

Water Authority-Cayman July 14, 2020 Letter Re: Major Groundwater Projects for Dart. Letter to Dart and APEC teams

Water Authority-Cayman

Incorporated by Law No.18 of 1982 in the Legislative Assembly of the Cayman Islands

14th July 2020

Mr. Frank O'Leary, Senior Construction Engineer, Dart, Frank.OLeary@dart.ky
Mr. Bryan Fitzgerald, Dart, Bryan.Fitzgerald@dart.ky
Mr. Andrew Small, Senior Manager Project Management, Dart, Andrew.Small@dart.ky
Mr. Martin Edelenbos, Engineering Coordinator SWM, Dart, Martin.Edelenbos@dart.ky
Mr. Denis P. Murphy, Senior Engineer, APEC Consulting Engineers Ltd, Denis@apec.com.ky
Mr. Ali Sabti BSc(Eng), Senior Civil and Structural Engineer, APEC Consulting Engineers Ltd, Ali@apec.com.ky
Mr. Pearse Murphy, Principal, APEC Consulting Engineers Ltd, Pearse@apec.com.ky

Re: Major Groundwater Projects for Dart

Dear Dart and APEC teams,

The Water Authority has been approached by Dart and APEC about the Water Authority's requirements and background information for various major groundwater projects proposed by Dart:

1. **ISWMS**, the Energy Recovery Facility for the Integrated Solid Waste Management System. Geothermal cooling, project location to be confirmed, initial proposal on 19A 4REM6, but site may have been relocated.
   Project contacts: Andrew Small and Martin Edelenbos, Dart and various staff of APEC.
2. **Laundry Facility**, Feedwater abstraction and disposal of brine for Reverse Osmosis Plant for Laundry Facility on 19A 4REM6.
   Project contacts Denis Murphy and Ali Sabti, APEC.
3. **Camana Bay,** Geothermal cooling for Camana Bay on 12E 115, location to be confirmed.
   Project contact Frank O'Leary, Dart.
4. **Ritz Carlton**, Geothermal cooling for Ritz Carton hotel on 12C 393, location to be confirmed.
   Project contact Ali Sabti and Denis Murphy, APEC.
5. **Indigo Hotel**, Geothermal cooling for Indigo Hotel on 11B 94 & 91.
   Project contact Ali Sabti and Denis Murphy, APEC

Rather than giving an individual reply for each project and providing the requested information to each of the project contacts, it is better to reply to all concerned at this stage because of the commonalities of the projects and because the groundwater use for each of these projects may impact existing and proposed use of groundwater.

P.O. Box 1104, Grand Cayman, KY1-1102, CAYMAN ISLANDS
P.O. Box 240, Cayman Brac, KY2-2002, CAYMAN ISLANDS
Website: www.waterauthority.ky

Tel No: 345-949-2837 Fax No: 345-949-0094
Tel No: 345-948-1403 Fax No: 345-948-1404
E-mail: info@waterauthority.ky

Please note that the Water Authority has not received basic information on proposed volumes of abstraction and disposal and the anticipated temperature of the cooling water that will be discharged for the geothermal projects. Also, we have not received information on the proposed volume of abstraction and disposal for the RO plant for the Laundry Facility. In addition, we are not sure about the locations of some of these projects.

Abstraction Licence and Discharge Permit under the Water Authority Law

Each of these projects is required to apply for an abstraction licence for the abstraction of groundwater and a discharge permit for the disposal of effluent under the Water Authority Law (2018 Revision), sections 22 and 34 respectively. Once we get further with the technical aspects of these projects, we will advise regarding the administrative process for the applications, inclusive advertising. Please be advised that the application process requires public consultation, therefore any technical reports that are part of the application may need to be available for public review.

If a project involves significant groundwater abstraction and disposal and there is potential impact on the groundwater resource, the Water Authority may require a hydrogeological study as part of the application process. This has been done for the Kimpton Seafire geothermal project, CUC groundwater cooling, the Government Administration Building geothermal project and the Camana Bay geothermal project. The hydrogeological study for the Camana Bay project was conducted by APEC on behalf of Dart in 2005, but the project was not carried out at the time. The Water Authority received the report, but as the project was not pursued the report has not been formally reviewed or accepted for that matter.

Existing and Proposed major Groundwater Projects that may impact each other

The proposed projects are unique, distinctive in nature, take place at different locations and are managed by different persons, but they all rely on the same groundwater resource. Also, there are already a number of existing groundwater projects that may be impacted by the new projects. For that reason, the Water Authority provides the attached inventory of existing and proposed groundwater projects that may be impacted by what is proposed (refer to attached excel spreadsheet and maps). The information is based on what the Authority has on record. Please note that the Authority will contact several developers (Cayman Water Company, Margaritaville and the Marriott) for updates on their groundwater usage. We would be grateful if Dart could confirm the status of the Dragon Bay and Camana Bay RO plants.

For each of the projects proposed by Dart the spreadsheet identifies existing and proposed projects within a radius of 2 km for the geothermal projects and 1.5 km for the RO project. Whereas these distances are arbitrary, it shows that there is a potential for the proposed projects to influence existing projects and/or each other. Although different studies may be undertaken for each proposed project, it is important that an overall evaluation is done whether the existing and proposed projects impact each other. If determined that the projects do not impact each other, separate studies for each project may suffice.

Proposed Study

The overall objective is to conduct a hydrogeological study to determine the most suitable well configuration (i.e. well depths and locations) in consideration of limiting and mitigating any medium- and long-term effects of abstraction and disposal on other groundwater users and the environment. Of specific concern is the impact of the discharge of the warmer cooling water and its potential impacts on groundwater used for other geothermal cooling projects and Reverse Osmosis plants, as increased feedwater temperature impacts the performance of RO plants. Also, where a project is close to the landfill, which has no liner, the well design needs to take potential impacts of landfill leachate into account.

In previous projects undertaken by Dart, such as the proposed landfill project in Bodden Town and the Kimpton Seafire geothermal cooling it engaged the service of APEC, who have worked closely with Dr. Brian Jones, Professor of Geology at the University of Alberta and Robert Minning and John Bomba of R.C. Minning & Associates. Whereas the Water Authority can only stipulate that qualified consultants need to be engaged, based on the track record and our experience with these consultants, there is a merit to involve them in the relevant studies.

The studies for CUC, Government Administration Building, Kimpton Seafire and Camana Bay involved the installation of pilot wells to collect geological samples, determined site specific properties and addressed the general geology and the site-specific geology of the project area. These studies also included site specific groundwater modelling for the geothermal projects.

Based on the overall potential impacts of the proposed projects, there is a need to review the existing reports and to identify gaps as additional development has taken place and more geological information has become available since these studies and reports were generated. We suggest that Dr. Jones is approached to provide his professional opinion on the existing geological reports to identify any additional work that needs to be undertaken to provide relevant and additional geological information for these projects. In a similar way we suggest that Robert Minning and John Bomba are consulted to provide their professional opinion on the existing hydrogeological reports for the geothermal projects to identify any additional work that needs to be undertaken to update and improve the predictive groundwater models for the proposed projects.

We suggest that they specifically provide their professional opinion on:

1. Need for additional site-specific investigations, i.e. is it necessary to install additional pilot wells to fill in gaps in the geological information available or other additional field work that they deem appropriate;
2. Need for additional information to develop an up to date groundwater model to predict the intermediate and long-term effects (1, 5- and 10-year predictions) of the cooling water abstraction and disposal.
3. Can the proposed projects be reviewed on an individual basis or is there a need for an overall approach that considers the specifics of all projects?

Once we have received their feedback, we can then determine the scope and need for further studies.

Consultation under the National Conservation Law

Please be advised that the proposed projects are subject to review by the National Conservation Council under the National Conservation Law, 2013. For the geothermal project for the ISWMS this process has already been initiated by the Environmental Impact Assessment for the ISWMS. Once we have the basic information for each of the other proposed project, such as specific location, abstraction and discharge volumes and temperature of cooling water, the Water Authority will contact the Department of Environment about their specific requirements for the other projects.

I trust this addresses the Water Authority's overall review and application process for the various groundwater projects proposed by Dart.

Yours sincerely,

Hendrik van Genderen
Water Resources Engineer

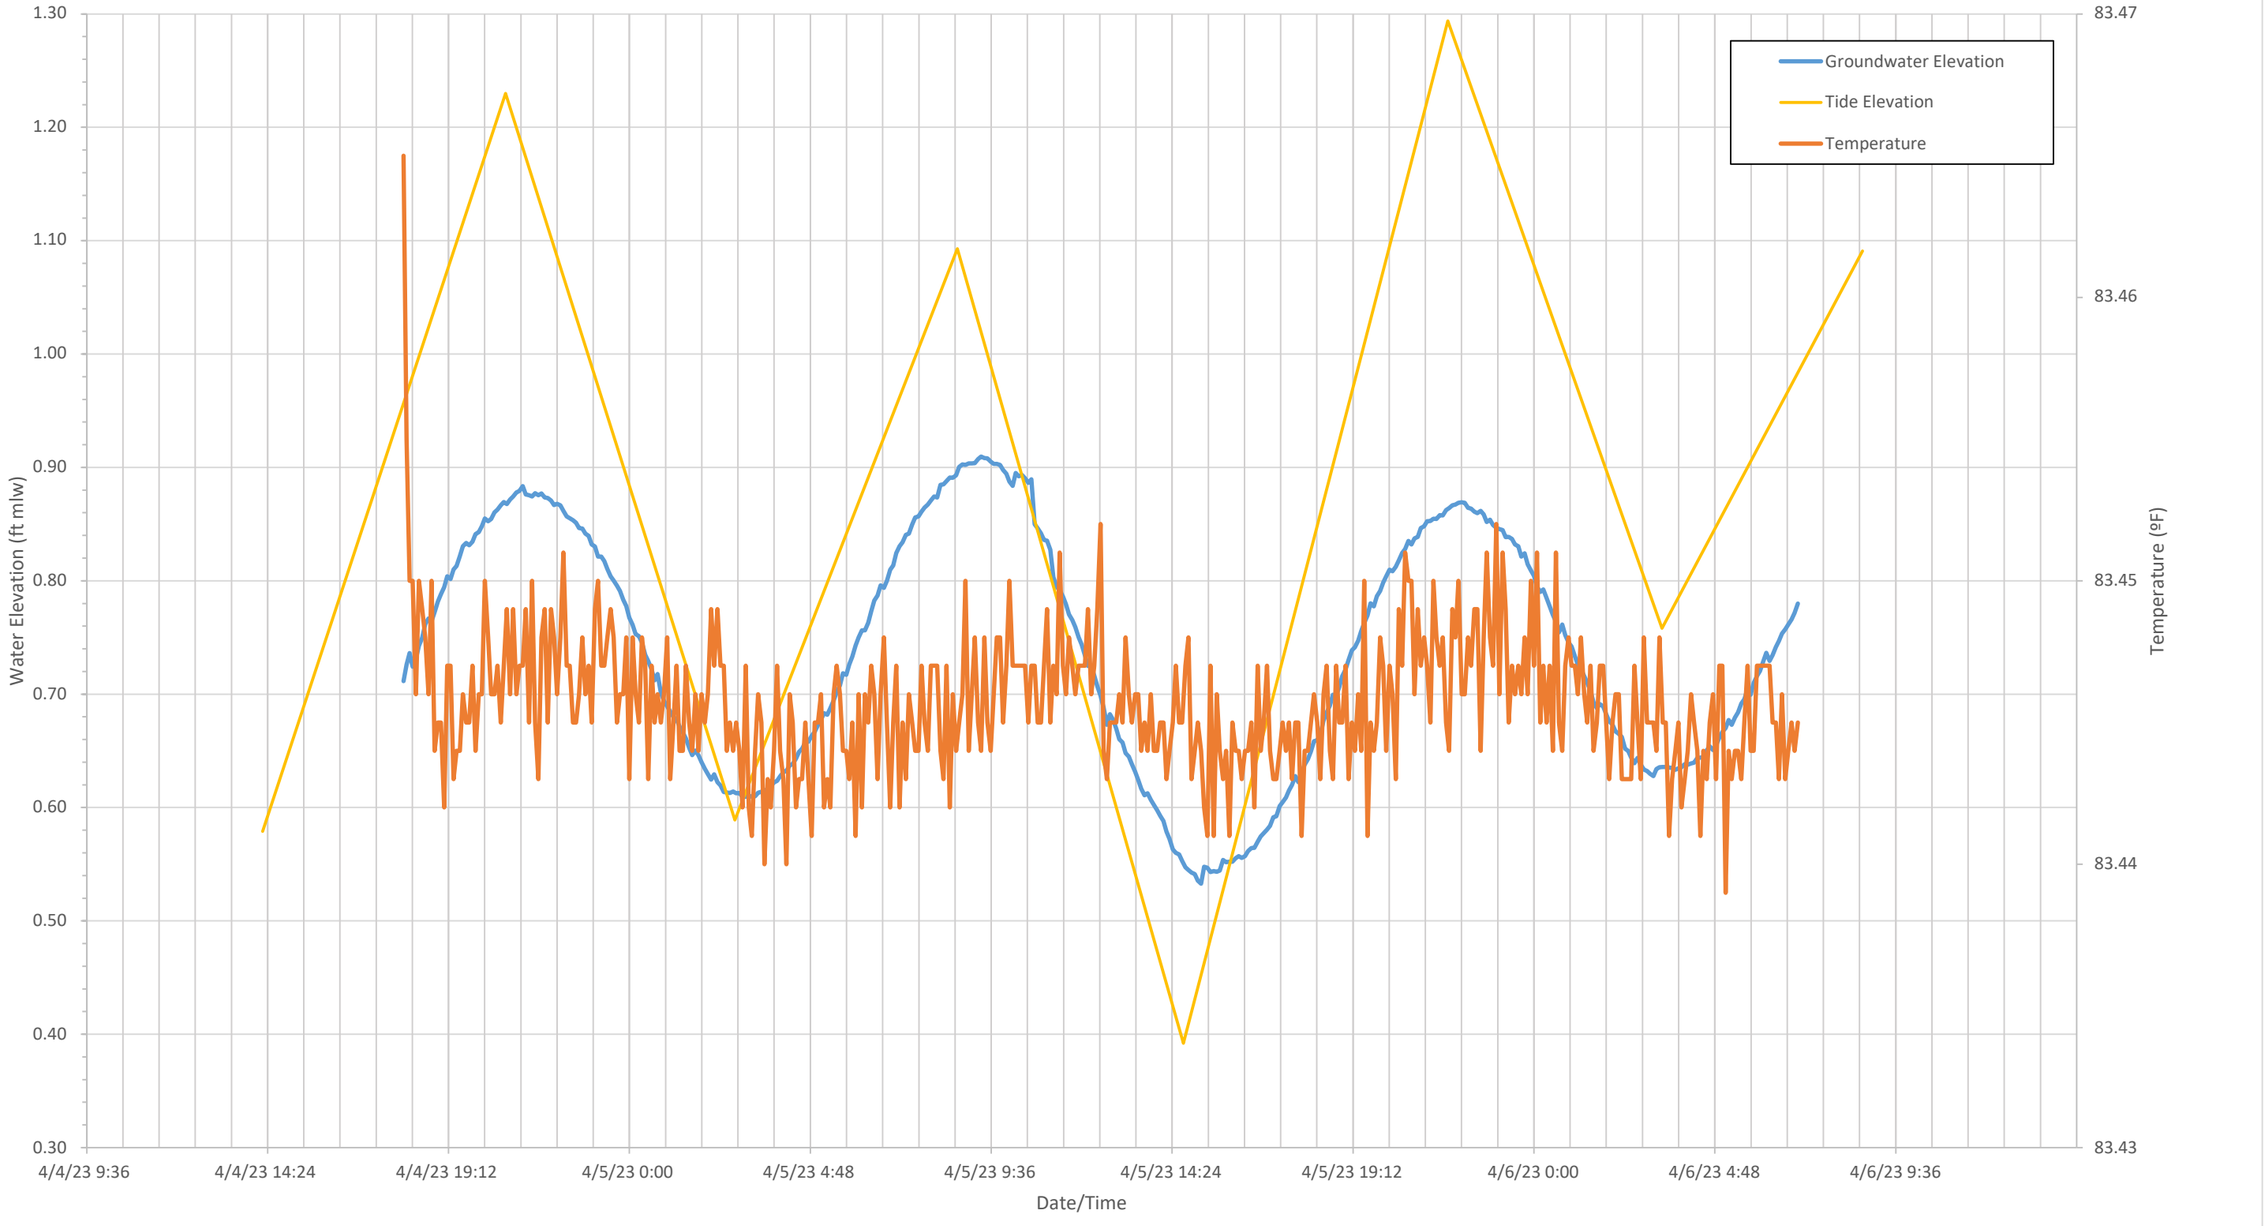
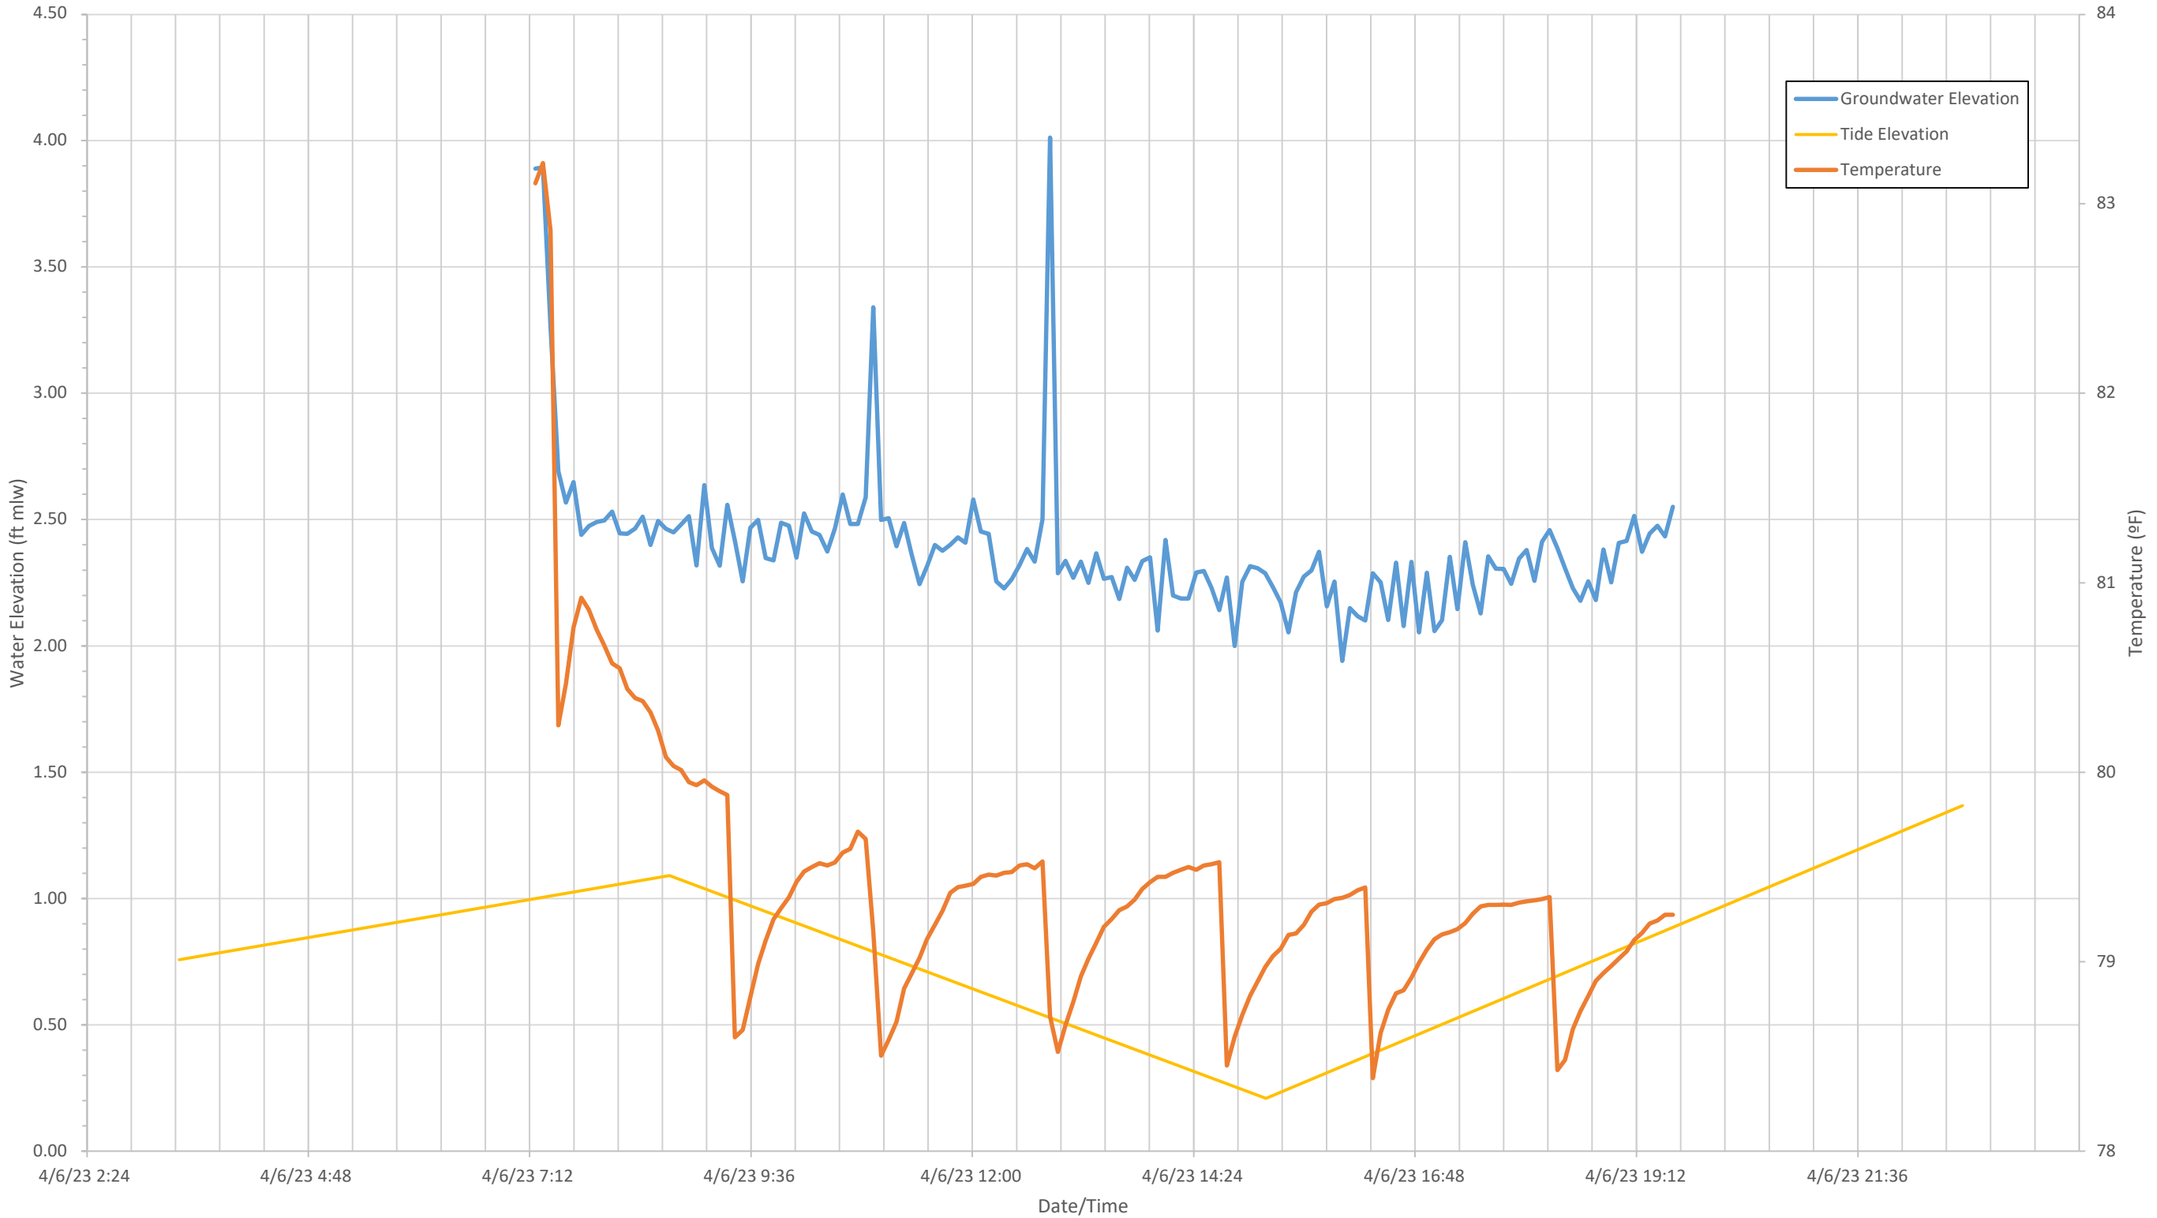
APPENDIX C



Analyses of Pumping Test Data

DUM-1 and DUM-3 PUMPING TEST ANALYSES

1. DUM-1 has a Total Depth of 407 ft with 250 ft of casing leaving 157 ft of open borehole. A sixty (60) hour pumping test was conducted on April 5 and 6, 2023 which consisted of a 24 hour rest-period (no pumping), a 12 hour pumping period followed by a 24 hour recovery period. Water level fluctuations during the entire test were recorded via a pressure transducer supplemented with periodic electric tape measurements to an established bench mark on the casing top. The pumping portion of the test was at a rate of 356 gallons per minute (gpm). The pre-test, pumping test and post (recovery)test water levels were plotted along with the corresponding tidal stage and groundwater temperature. These plots are presented on the attached graphs. The static water level just prior to the start of the test was ~ -3.9 ft below the top of casing (TOC) and "stabilized" at ~ -2.4 ft below the TOC. However, a review of the tide chart for the test period showed a number of full tidal periods occurred during the test period. The corresponding specific capacity (SC) is equal to the pumping rate "Q" in GPM divided by the measured drawdown "s" which in this case is 356 GPM/1.5 ft = 237 GPM / foot of drawdown. The theoretical drawdown at Q = 1,000 GPM would be 1,000/237 = 4.2 ft and at 2,000 GPM it would be twice that or 8.4 ft. Note that the well was only pumped at 356 GPM so in reality we do not know what the response would be to the higher pumping rates. Since the -250 ft to -407 ft interval will be the injection zone, i.e., receiving water, the projected drawdown becomes the head needed for the particular injection rate.



2. DUM-3 has a Total Depth of 147 ft with 50 ft of casing leaving 97 ft of open borehole. A five (5) hour pumping test was conducted on March 16, 2023, at an extraction rate of 356 gallons per minute (GPM). The static water level at 1:10pm, just prior to the start of the test was -99 inches below the top of casing (TOC). Pumping began at 1:15pm and continued for five (5) minutes at which time the pumping level is reported to have stabilized at 119 inches below the TOC. The pumping level at the end of the test was -114 inches below TOC for an apparent drawdown of 15 inches (114 inches – 99 inches). A review of the tide chart for the test day showed that the tide was falling during the test period. The apparent rise in the pumping level during the test could be due to the lag time between tidal levels in the ocean or North Sound and the water level response in DUM-3. Therefore, a conservative approach was used which attributes the maximum measured drawdown of 1.67 ft (119 inches – 99 inches/12) to the pumping of the well. The corresponding specific capacity (SC) is equal to the pumping rate "Q" in GPM divided by the measured drawdown "s" which in this case is 356 GPM/1.67 ft = 212.6 GPM / foot of drawdown. The theoretical drawdown at Q = 1,000 GPM would be 1,000/212.6 = 4.7 ft and at 2,000 GPM it would be twice that or 9.4 ft. Note that the well was only pumped at 356 GPM so in reality we do not know what the response would be to the higher pumping rates.

1. Introduction

1.1 Purpose

The purpose of this study is to estimate the flood elevations due to hurricane-induced storm surge for a proposed Integrated Solid Waste Management System (ISWMS) development in the Cayman Islands. This report summarizes the development and calibration of a coastal model that simulates storm surge elevations resulting from hurricane events that are based on three exposure categories outlined in the Terms of Reference (Wood, 2021).

1.2 Project Location

The ISWMS comprises approximately 30 acres and is located on the western coast of Grand Cayman highlighted by the orange boundary, north of George Town (Figure 1).

Figure 1 Project Vicinity Map

2. Model Setup

2.1 Introduction

The DHI MIKE software package was utilized to simulate the storm surge elevations, specifically an integrated hydrodynamic and wave model. The process involved the setup and calibration of the model using publicly available, high water mark elevations generated by Hurricane Ivan (FEMA, 2005). The model inputs, modelling tools, and model outputs are described in the flow chart provided in Figure 2.

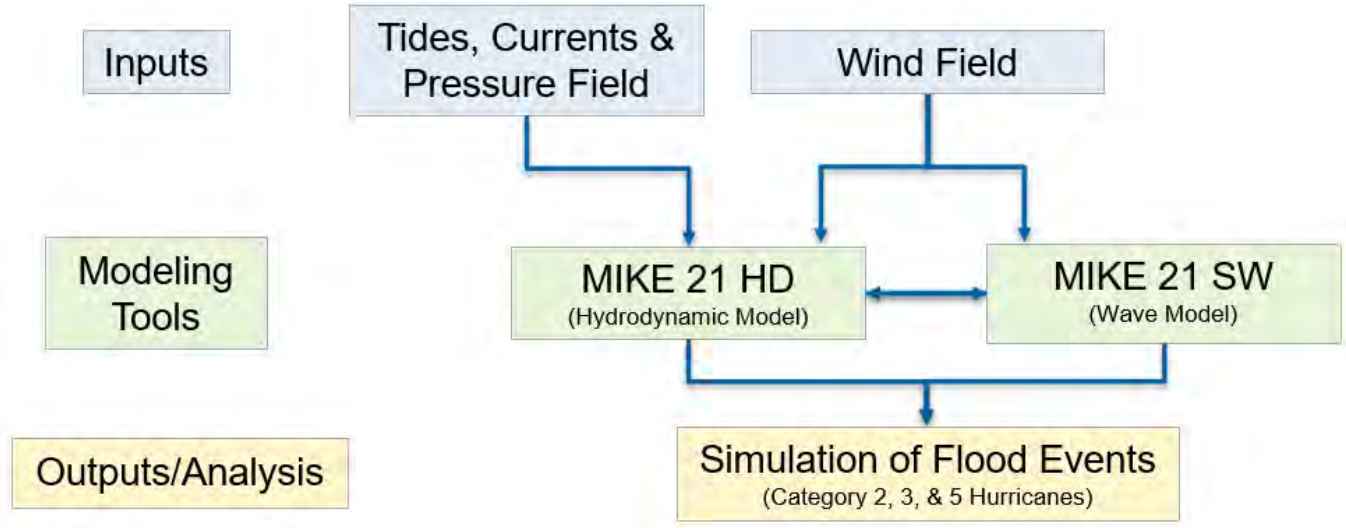

Figure 2 Modelling Flow Chart

2.2 Modelling Framework

The first step in the model setup was to develop a framework that ensures consistency throughout the project's lifetime. The modelling framework considers parameters such as the extent of the project area, type of software used, knowledge of local bathymetry, topography, hydrodynamic and wave climates, and availability of measured data sets required to both drive the model and validate its results. Table 1 provides a summary of the overall modelling framework used for the hydrodynamic and wave model calibration.

Table 1 Modelling Framework

Item	Detail
Model Datums	Horizontal Datum: Lat/Long, WGS84 Vertical Datum: MSL
Model	MIKE 21 HD, MIKE 21 SW, MIKE 21 Cyclone Wind Generator
Calibration Data	Hurricane Ivan High Water Mark Elevations (FEMA, 2005) Hurricane Ivan Best Track Data (NOAA, 2021)
Model Domain	Base Mesh: North Carolina v6c ADCIRC (ADCIRC, 2021) Offshore Boundary: 60° W Longitude Land Boundary: North & South America
Model Geometry	The mesh resolution is finest along the shoreline of interest (Grand Cayman). In general, the mesh resolution is as follows: – Grand Cayman Shoreline: 1 km

Item	Detail
	– Gulf of Mexico & Caribbean Sea: 30 – 35 km – Atlantic Ocean: 80 km
Hurricane Data	The model simulates three synthetic hurricane events based on the exposure categories outlined in the ToR (Wood, 2021) using the following parameters. – Best Track Data – Hurricane Ivan (NOAA, 2021) – Radius to Maximum Winds – Hurricane Ivan (NOAA, 2021) – Maximum Wind Speed – Saffir Simpson Scale • Category 2 (110 mph) • Category 3 (129 mph) • Category 5 (157 mph) – Central Pressure – Saffir Simpson Scale • Category 2 (965 millibars) • Category 3 (945 millibars) • Category 5 (919 millibars)
Elevation Data	Offshore: Bathymetry from ADCIRC mesh Grand Cayman: MERIT DEM (Yamazaki et al, 2018)

2.3 Model Input Parameters

2.3.1 Model Domain

GHD's model domain and mesh was developed using a previously validated ADCIRC model mesh (ADCIRC, 2021). The mesh extends over the North Atlantic from the coast of North and South America up to the 60° W parallel and comprises 58,369 elements and 31,435 nodes and is used by the United States (US) Department of Homeland Security to forecast storm surge ahead of hurricane events and by the US Federal Emergency Management Agency (FEMA) to update the National Flood Insurance Program coastal inundation maps. This mesh was further refined in the area of interest surrounding Grand Cayman Island and the ISWMS project site. The final mesh comprises 60,087 elements and 32,351 nodes with mesh resolutions as fine as 1 km along the Grand Cayman shoreline (Figure 3).

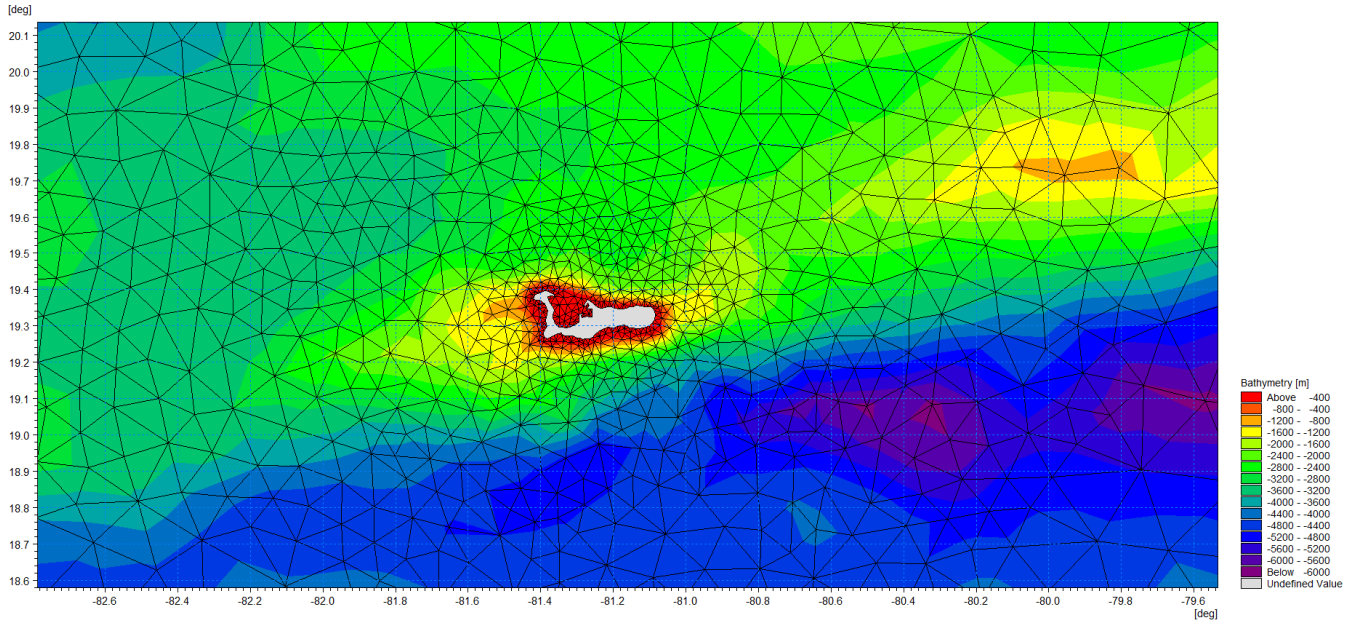

Figure 3 Mesh Refinement and Incorporation of Grand Cayman

2.3.2 Boundary Conditions

The coupled MIKE 21 HD and SW model was forced at a single offshore boundary using a 0.125° x 0.125° resolution global tide model with 8 tidal constituents. Space and time-varying hurricane wind and pressure fields obtained from the MIKE 21 Cyclone Toolbox were used as forcing across the domain. These two model boundaries are listed in the bullets below and depicted spatially in Figure 4.

1. Water surface elevations are used to drive the model's offshore, eastern boundary. The tidal information is based on DHI's global tide model which is available at a resolution of 0.125° (~8.6 miles). The tidal conditions include contributions from 4 semidiurnal constituents (M2,S2,K2,N2) and 4 diurnal constituents (K1, O1, P1, Q1).

Wind and pressure fields generated from the MIKE 21 Cyclone Toolbox for the scenarios depicted in Table 2.

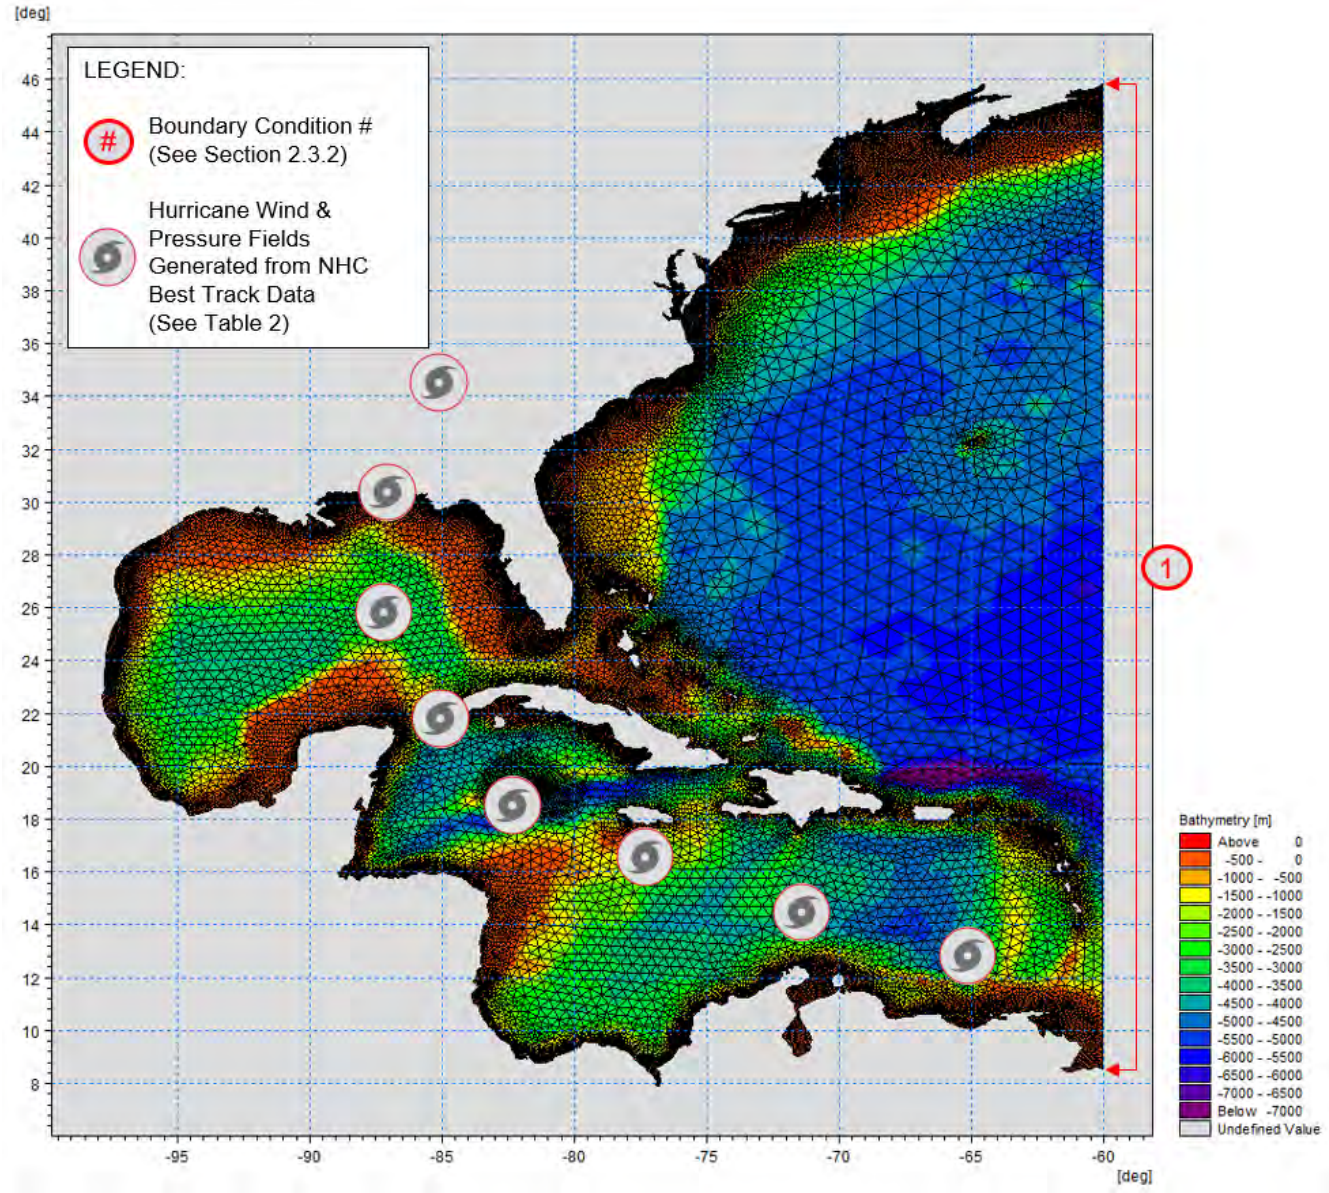

Figure 4 Model Domain & Boundary Condition Schematic

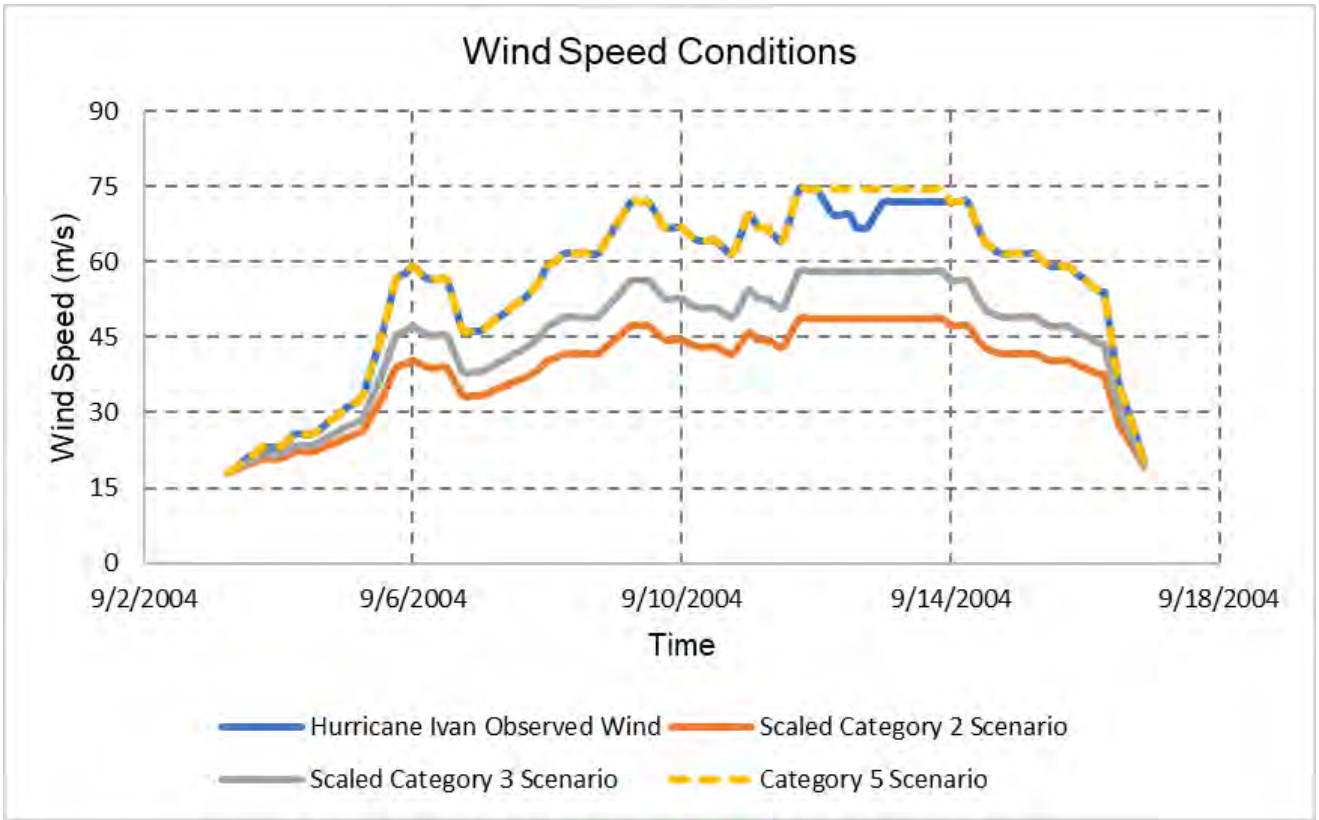
2.3.3 Forcing Conditions



For the purposes of model calibration and the evaluation of shifting the track of Ivan to the north of Grand Cayman (runs 1 and 2 respectively), the native wind and pressure conditions of Hurricane Ivan obtained from observational data were used as input to the parametric cyclone model. In the cases of the Category 2 and 3 scenarios (runs 3 and 4 respectively), scaling of the wind and pressure timeseries is necessary. In these instances, the maximum wind speed and minimum central pressure based on the Saffir-Simpson scale (Table 3) was used as the storm passed Grand Cayman to provide the most conservative conditions for a storm of that Category. For the Category 5 scenario, the maximum observed wind speed and minimum observed central pressure was specified as a constant value while the storm is passing the island of Grand Cayman. A timeseries of wind speed and central pressure for all scenarios is displayed in Figure 5.

Table 2 Hurricane Model Parameters by Scenario

Run #	Description	Parametric Model	Best Track & Ground Speed	Wind Speed (mph)	Central Pressure (millibars)	Wind Friction
1	Calibration	Holland, Single Vortex	Hurricane Ivan (NOAA, 2021)	Varies, up to 167 mph	Varies, down to 910 mb	Linear Variation from 0.00125 – 0.0025
2	Track shifted north of Grand Cayman	Holland, Single Vortex	Hurricane Ivan (NOAA, 2021). Track shifted 1° to the north	Varies, up to 167 mph	Varies, down to 910 mb	Linear Variation from 0.00125 – 0.0025
3	Category 2 Hurricane	Holland, Single Vortex	Hurricane Ivan (NOAA, 2021)	Scaled to a maximum 110 mph	Scaled to a minimum 965 mb	Linear Variation from 0.00125 – 0.0025
4	Category 3 Hurricane	Holland, Single Vortex	Hurricane Ivan (NOAA, 2021)	Scaled to a maximum 129 mph	Scaled to a minimum 945 mb	Linear Variation from 0.00125 – 0.0025
5	Category 5 Hurricane	Holland, Single Vortex	Hurricane Ivan (NOAA, 2021)	Varies, up to 167 mph	Varies, down to 910 mb	Linear Variation from 0.00125 – 0.0025

Table 3 Saffir-Simpson Hurricane Scale

Saffir-Simpson Category	Maximum Sustained Wind Speed			Minimum Central Pressure (mb)
	(mph)	(m/s)	(kt)	
1	74-95	33-42	64-82	> 980
2	96-110	43-49	83-95	979-965
3	111-130	50-58	96-113	964-945
4	131-155	59-69	114-135	944-920
5	156+	70+	136+	< 920

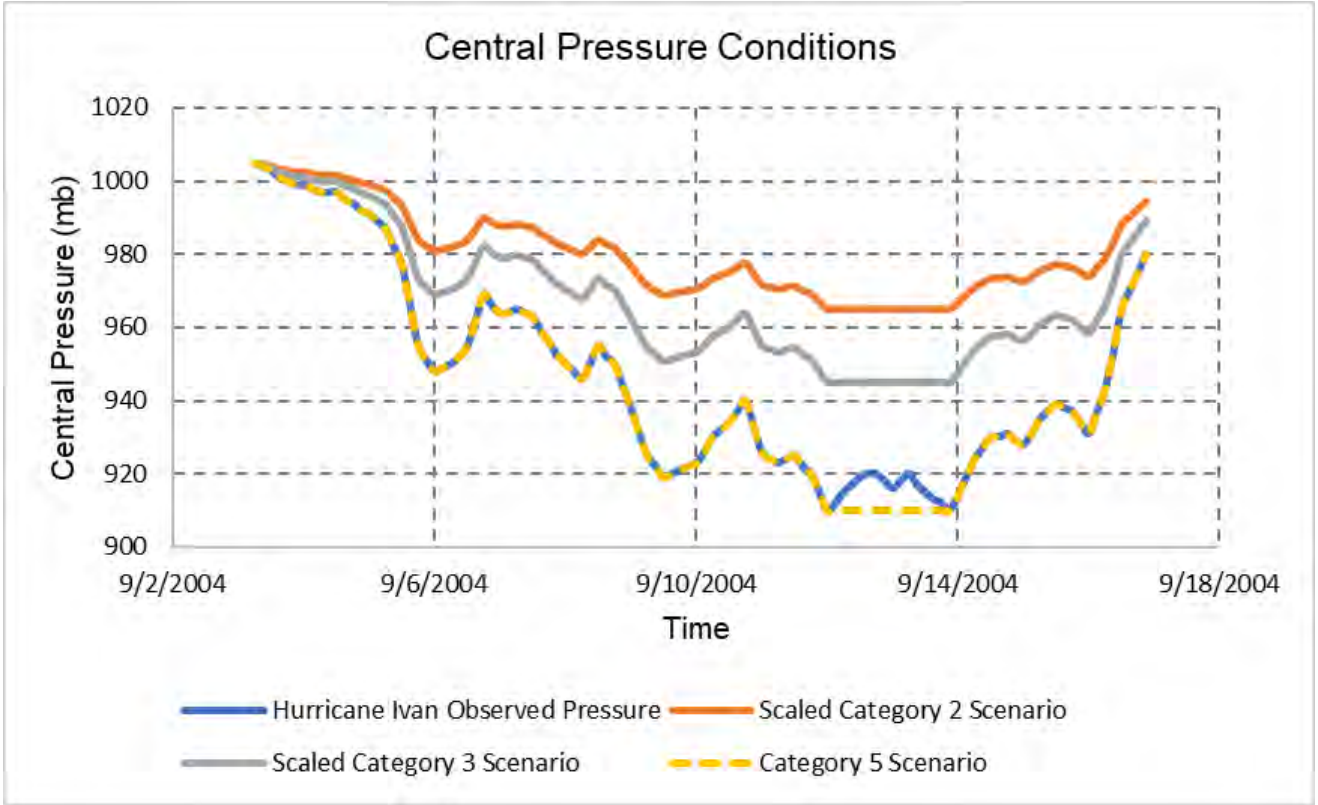


Figure 5 *Wind Speed and Central Pressure Conditions*

3. Model Calibration

Verification of a model is a multi-step process of model adjustments, or calibrations, and comparison of modelled parameters versus measurements or previously validated model results. For this model, storm surge calibration and validation were evaluated through visual comparison of the model outputs to the measured and predicted data along with quantitative comparisons. This was performed using:

– Plan view maps comparing the modelled storm tide to a visual output from a NOAA SLOSH model (Figure 7).
– Plan view maps comparing the modelled storm tide to a previously validated ADCIRC model (Figure 8).
– Comparison of modelled storm tide to measured high water marks (HWM) surveyed by FEMA.
– Comparison of modelled storm tide to a BSRC storm surge model for Hurricane Ivan performed by the Florida Department of Environmental Protection (FDEP).

3.1 Calibration Data and Parameters

The model calibration was performed by simulating the storm surge generated by Hurricane Ivan, which formed on September 4, 2004, reached Grand Cayman as a Category 4 hurricane on September 12, 2004 and made landfall in the United States near Mobile, Alabama as a Category 3 hurricane on September 16, 2004.

The radius to maximum winds (RMW) is a parameter required by the parametric model to generate a realistic hurricane structure that captures the wind field extent and distribution of the simulated storm. Generally accepted estimates for the RMW are based on distance to the 50-kt wind speed contour. The published range for the RMW varies from $0.15R_{50}$ to $0.35R_{50}$ (Takagi and Wu, 2016). The calibrated value utilized in the current modelling is the median value of $0.23R_{50}$ which corresponds to a radius of approximately 29 miles at time of landfall near Mobile, AL. This corresponds well with a RMW of 28 miles reported by (Stewart, 2005) which is used as the basis of a storm tide model of Hurricane Ivan presented in (FDEP, 2005).

A calibration of wind friction was necessary to capture the wind induced setup along the coastal areas where landfall occurred. A linear variation of wind friction based on the wind speed was found to be the most appropriate. Values ranged from 0.00125 for wind speeds of 7 m/s and below to a maximum value of 0.0025 in areas where the wind speeds exceeded 25 m/s. These values agree well with the results of field and laboratory tests presented in Figure 6 (Curcuc and Haus, 2020). Finally, local refinement of the shoreline bathymetry based on NOAA navigational charts near the landfall area were implemented to capture the peak surges observed along the seaside shoreline (NOAA, 2021a).

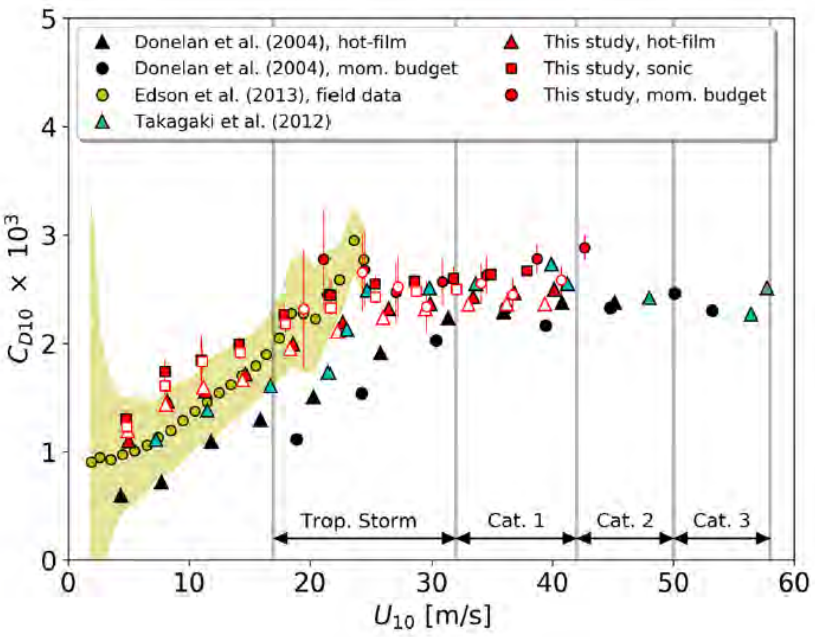

Figure 6 *Field and Laboratory Reported Wind Drag Coefficient Values*

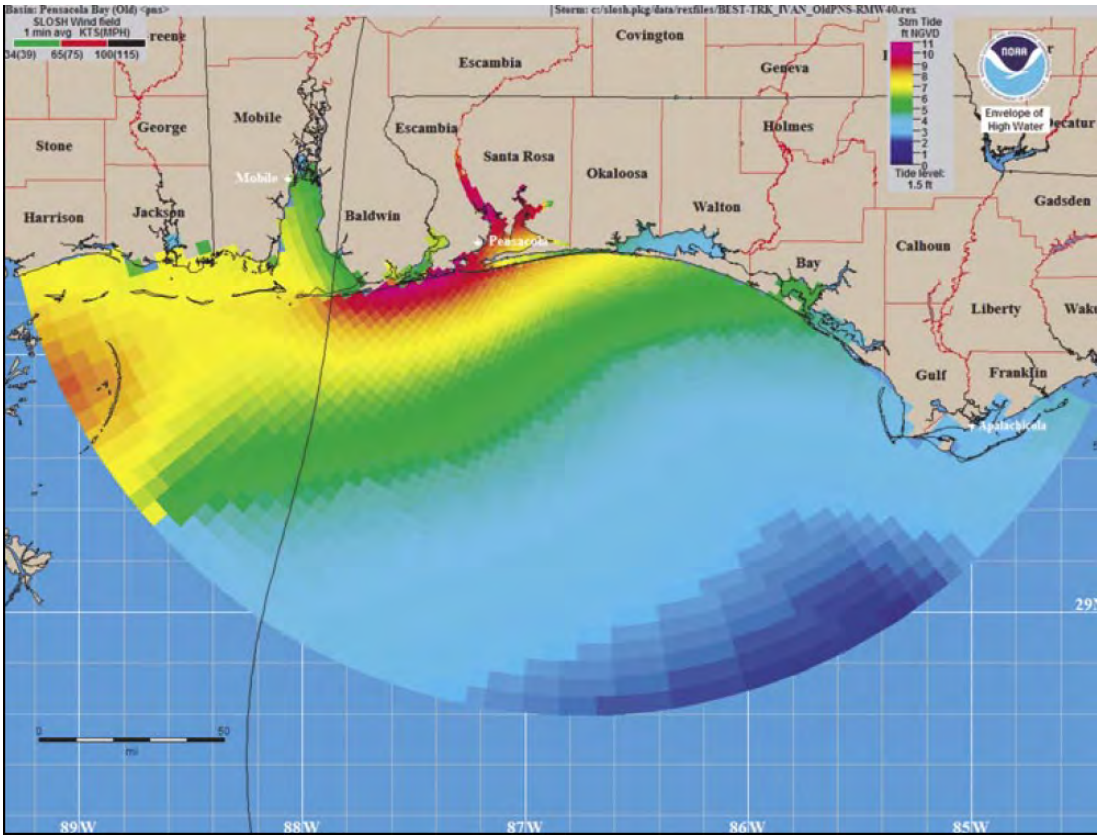

Figure 7 *Hurricane Ivan Envelope of High Water Calculated by NOAA SLOSH Model (ft, NGVD) (FEMA, 2005)*

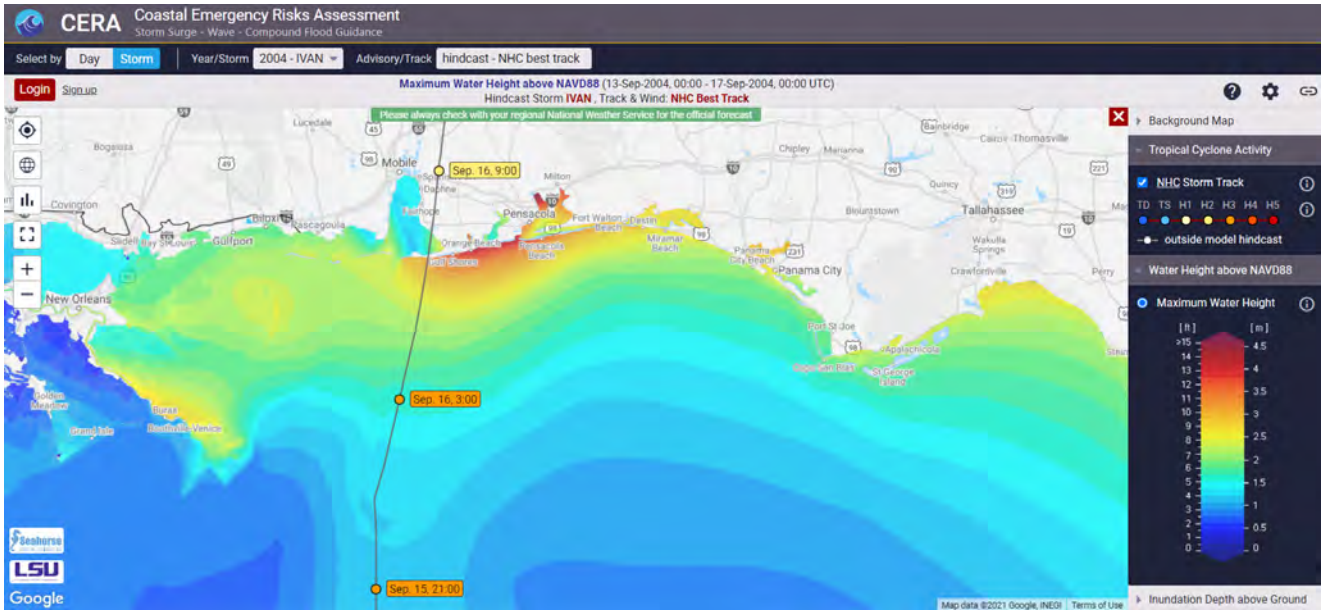

Figure 8 Hurricane Ivan Maximum Water Elevations (ft, NAVD-88) from ADCIRC Model (CERA, 2021)

3.2 Surge Elevations

The maximum simulated storm surge occurs just east of Hurricane Ivan's track local to the Gulf Shores area. Figure 8 displays the maximum modelled water surface elevations from Harrison County in Mississippi to the eastern border of Jefferson county in the Florida panhandle for purposes of comparison to the NOAA SLOSH and ADCIRC models on Figure 7 and Figure 8, respectively. The model accurately reproduces the effect of the pressure setup along the storm's path and the subsequent structure of the surge along the coastline with some of the highest surge values occurring in the Gulf Shores area and along Pensacola beach. The Pensacola and Perdido back bay area's exhibit similar tendencies to both the SLOSH and ADCIRC models with the highest water surface elevations occurring at the limits of the bay areas. The maximum simulated surge values agree well with the results from the ADCIRC model on the order of ~13-15 ft over the National Geodetic Vertical Datum of 1929 (NGVD). The maximum reported water surface elevation from the NOAA SLOSH model is lower at ~11 ft, NGVD. The SLOSH model takes into account the effect of atmospheric pressure, size, track, and speed of the storm system but does not explicitly resolve or account for wave induced setup (NOAA. 2021c). This can contribute to the lower surge elevations displayed on Figure 7. The modelled storm surge is reported in feet over NGVD for the purpose of comparison to Figure 7 and survey data presented in Table 4. The difference between NGVD and MSL within the area shown on Figure 9 is ~0.5ft on average (NOAA, 2021d).

Destin-3**	30.38423	-86.47846	13.4	-	8.5
Destin-4	30.37097	-86.33866	10.2	-	8.3

*hyphen denotes no value calculated by the BSRC model given at this location

**Surveyed HWM displays survey error (FDEP, 2005)

The modelled storm surge elevations agree well with both the observed HWM and BSRC modelled storm tide elevations along the US coastline impacted by the landfall of Hurricane Ivan. Modelled storm tide elevations from both the current modelling and BSRC reported values were generally less than the HWM survey data. This is prominent at locations Ft. Walton Beach-1 and Destin-3 where the survey data displays error (FDEP, 2005). The model underestimates the maximum surges in the back bay and lagoon side of Pensacola which can largely be attributed to the coarse bathymetric resolution of the mesh in those areas. Due to the location of the project area being situated on Grand Cayman, which is a highly exposed Caribbean Island, surges will not have to be resolved through complex coastal inlets and extensive back bay areas. For these reasons the model's performance is acceptable.

4. Results

The coastal flood elevations (storm surge + wave setup) are presented in the following section. Each scenario is generated based on the parameters and descriptions presented in Table 2. The results are presented by figures of the spatial distribution of the maximum water surface elevations experienced under the conditions of each scenario. The elevations are referenced to meters above local mean sea level (LMSL).

4.1 Track Comparison

Prior to the execution of the Category 2, 3, and 5 scenarios, a comparison of surges resulting from storm path variability was conducted. In the case of Run 2 (Table 2), the best track data of hurricane Ivan was shifted north by 1° of latitude along its entire extent to compare the surges produced by the actual trajectory of Hurricane Ivan which passed to the south of Grand Cayman versus the same storm passing to the north. Figure 11 displays the storm's best track path (red) and the offset track (pink) with Grand Cayman Island positioned in the middle.

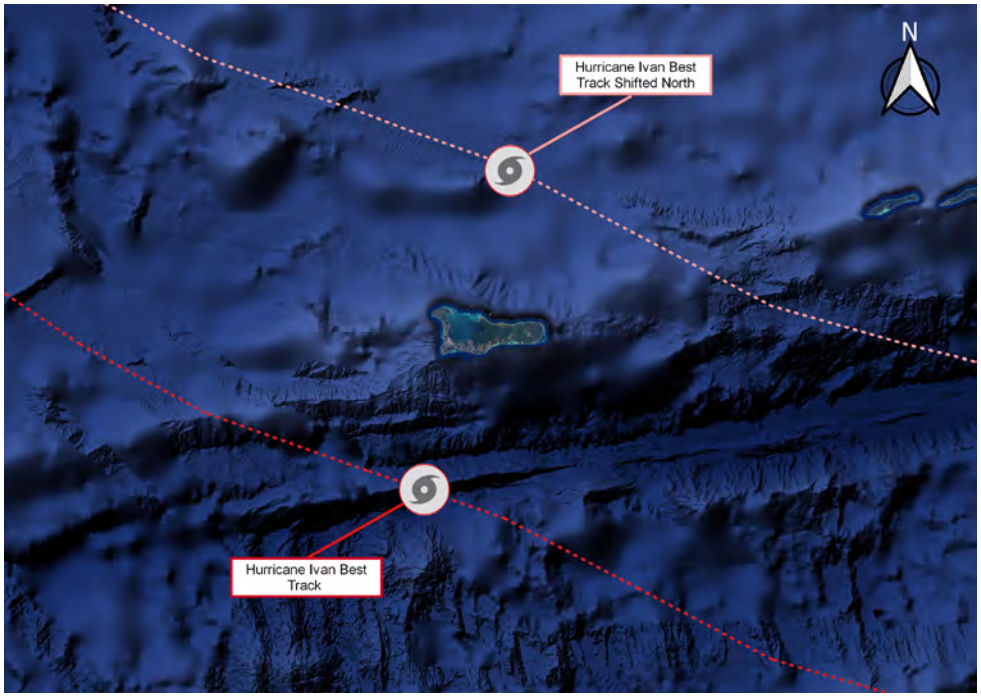

Figure 11 Best Track Comparison

The computed surges resulting from the two paths were compared to determine which case is more severe along the Grand Cayman shoreline adjacent to the ISWMS Development Site. It was found that the actual best track results in higher storm surge elevations at the site. The counter clockwise (CCW) rotation of the storm coupled with Grand Cayman being positioned in the right-hand sector of the storm exposes the island to higher wind velocities attributed to the southeast-northwest movement of the storm. The actual best track was used in the scenarios described in the following sections.

4.2 Category 2 Scenario

Maximum water surface elevations resulting from category 2 conditions generally range from 0.2 to 0.4m (1.3 - 2 ft) around the northern and western portions of Grand Cayman with slightly larger surges experienced around the south-eastern portion of the island. The most severe surge occurs in the north bay area with elevations peaking at 1.8m (5.9 ft) (Figure 12).

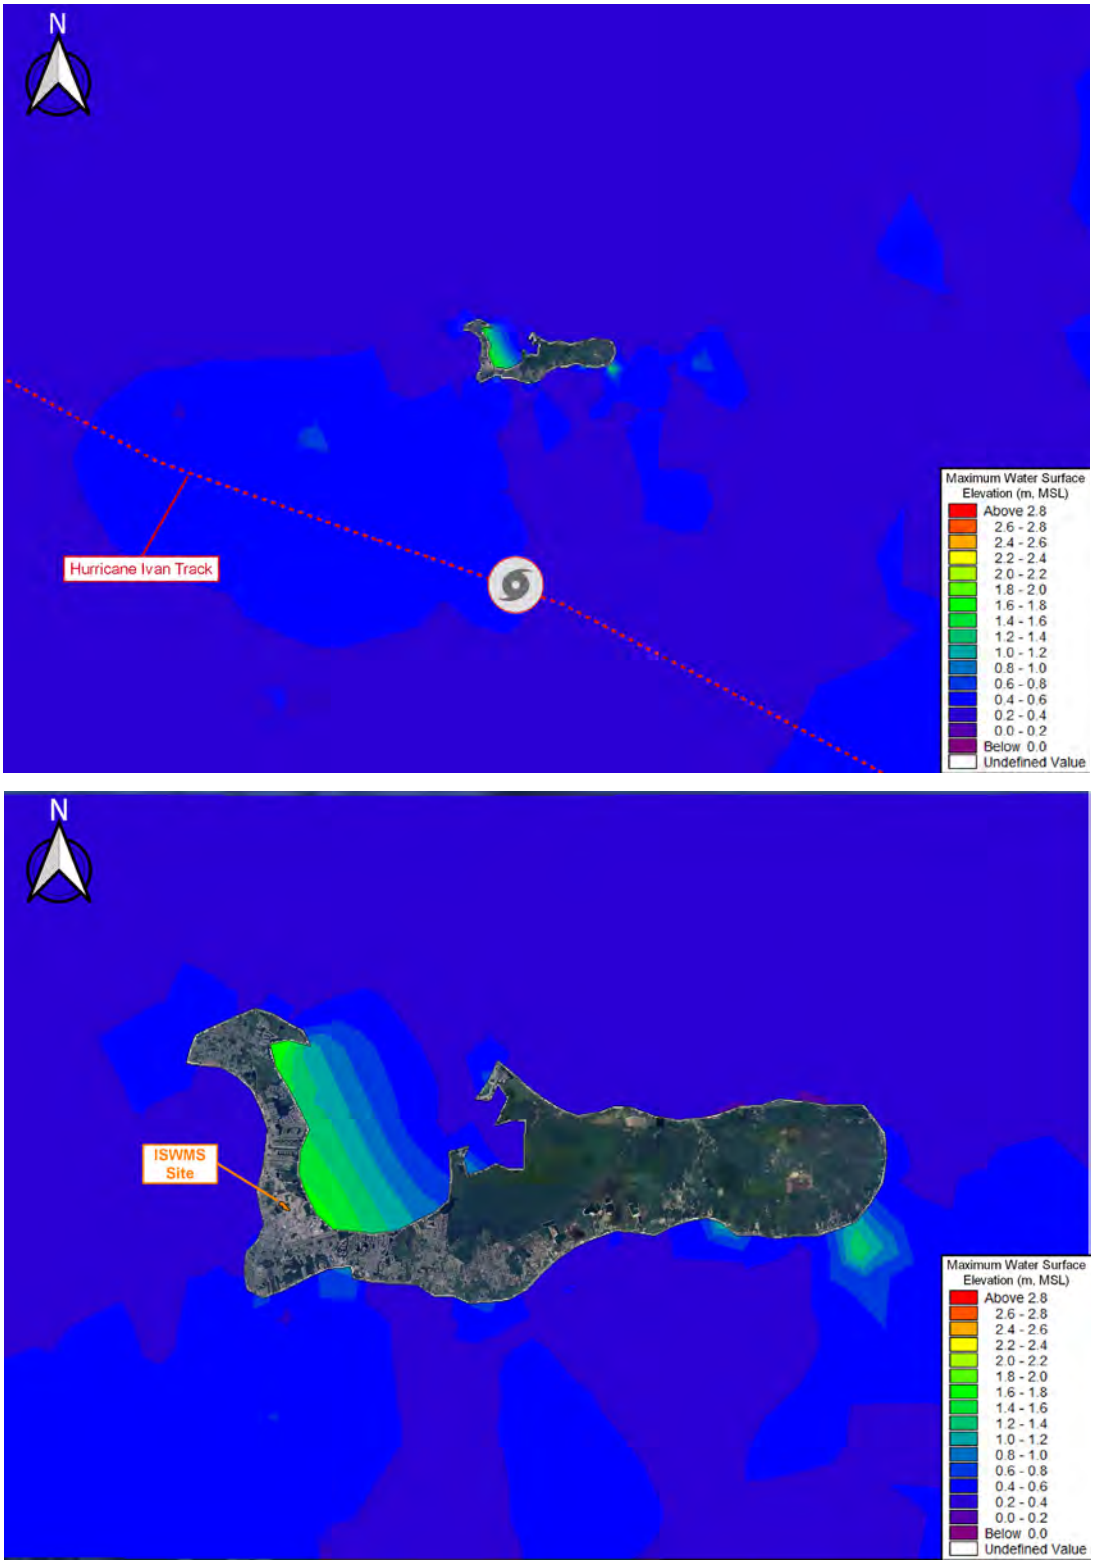

Figure 12 ***Far field (top) and near field (bottom) maximum water surface elevations under Category 2 conditions***

4.3 Category 3 Scenario

Similar water level tendencies are observed under category 3 conditions with the western and northern portions of Grand Cayman experiencing the least intense storm surges generally varying between 0.2 – 0.4m (1.3 - 2 ft). The northern bay is subject to similar maximum water levels that peak around 1.8m (5.9 ft) across the majority of the western interior bay shoreline (Figure 13).

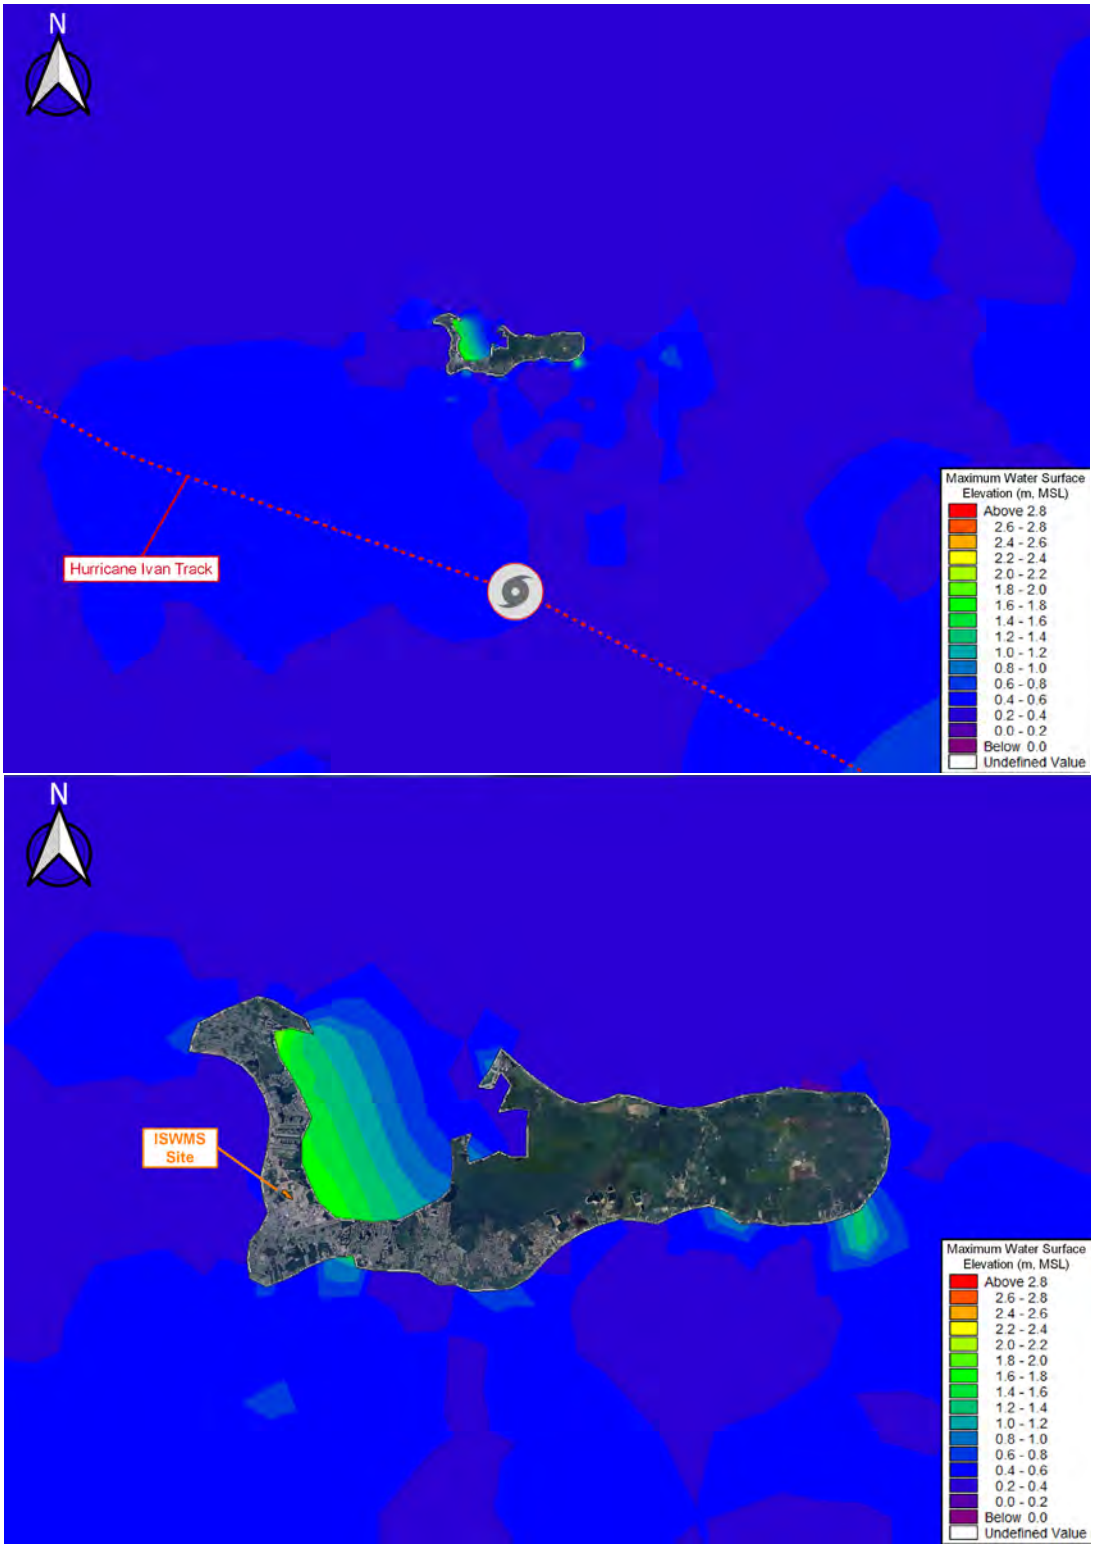

Figure 13 *Far field (top) and near field (bottom) maximum water surface elevations under Category 3 conditions*

4.4 Category 5 Scenario

The effects of pressure induced setup are highly distinguishable under category 5 forcing conditions (Figure 14). Wind and breaking wave setup increase the surge to between 0.4 -0.6m (1.3 - 2 ft) along much of Grand Cayman's western,

southern, and eastern shorelines. The storm surge experienced in the north bay reaches a maximum of approximately 2.8m (9.2 ft) which agrees well with reported surges between 8-10ft in this area (ECLAC, 2004)

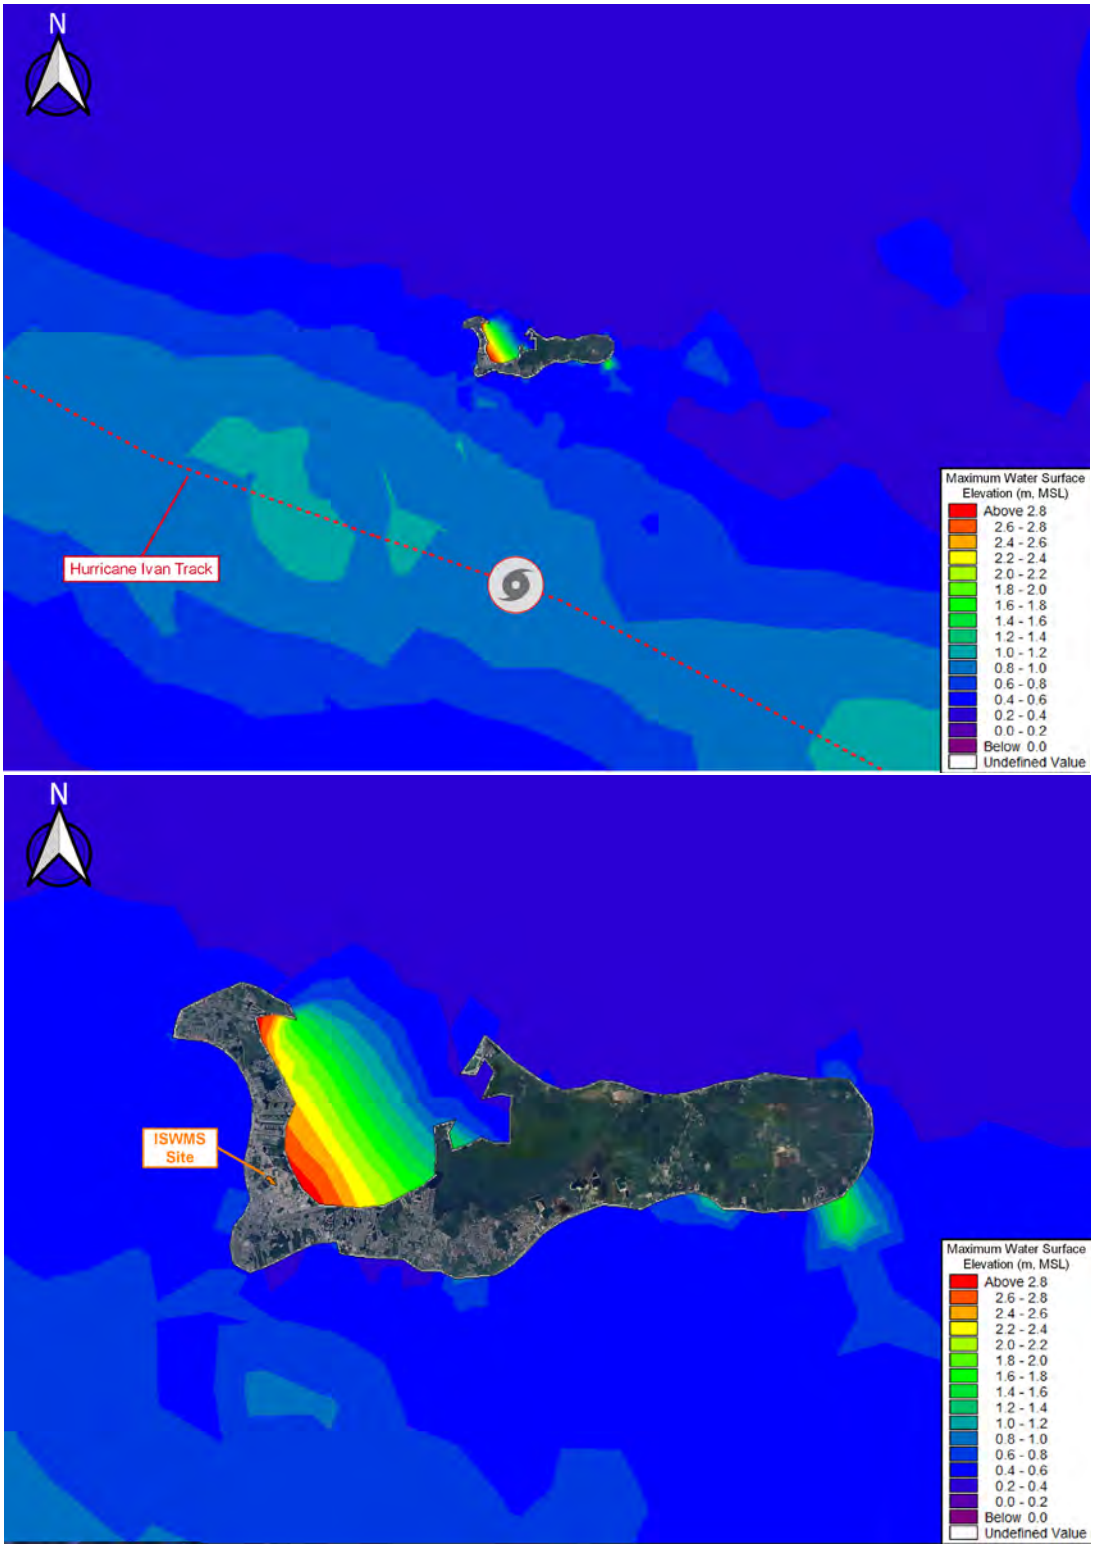

Figure 14 ***Far field (top) and near field (bottom) maximum water surface elevations under Category 5 conditions***

5. Conclusions

Hurricane Ivan was selected for use in the current modelling due to its proximity to Grand Cayman, the island on which the proposed ISWMS site is located, and it is categorized as one of the most powerful storms to impact the Caribbean, and Grand Cayman in particular, in recent years (ECLAC, 2004). A summary of maximum coastal storm surge per scenario is listed in Table 5 below:

Table 5 Maximum Storm Surge Adjacent to ISWMS

Scenario	Maximum Surge Adjacent to ISWMS site (m, MSL)	General Location of Occurrence
Category 2	1.7 (5.6 ft)	Western side of North Bay
Category 3	1.8 (5.9 ft)	Western side of North Bay
Category 5	2.9 (9.5 ft)	Western side of North Bay

The results of this study indicate the following:

– The most severe storm surge conditions due to wind, pressure, and wave setup occur in the interior of the north bay. This corresponds with previous coastal storm modelling efforts that attribute much of the coastal flooding in the north bay area to the wave setup and CCW wind structure of the passing storm (Baird, 2015).
– Water surface elevations under category 2 and 3 conditions are similar in distribution and peak values (~1.7-1.8 m)
– Category 5 conditions produce the largest surges around the island peaking at 2.9 m within the North Bay.
– The generally steep bathymetric geometry surrounding much of Grand Cayman contributes to lessening the severity of the surges experienced on the shoreline
– Maximum water levels varied from approximately 0.2 to 0.8 m in the worst case along the open shorelines of the island
– The North Bay area of Grand Cayman is suspectable to significant surge effects due to its shallow bathymetry and semi-enclosed geometry
– It is worth noting that compound flood effects such as coastal storm surge combined with extreme rainfall can exacerbate flooding. This is relevant in the case of Hurricane Ivan where records indicate that Ivan dumped between 15-18 inches of rainfall over the course of hours as the storm passed (GeoSY Ltd, 2004)
– It may be desirable in future work(s) to consider the effect of extreme rainfall associated with storm events in a coupled coastal hydrodynamic-precipitation model to obtain a comprehensive view of compound flooding on Grand Cayman
– The location of the ISWMS site exposes it to coastal flood inundation coming from the north bay to the east if a storm similar to Ivan were to occur. Generally, a storm surge event that tends to produce higher water surface elevations on the eastern side of the bay may be more threatening to the ISWMS.

March 29, 2023

SUMMARY

This report details the subsurface geology of the ReGen site that is located on the western part of Grand Cayman close to the George Town Landfill that is situated near George Town. The geology of this area is assessed baed on three wells (DUM-1, DUM-2, DUM-3) that were drilled to various depths and comparison with available information from other wells in the surrounding area. The following points encapsulate the main aspects of this area.

- Wells DUM-1, DUM-2, and DUM-3, were drilled to depths of 407.25 ft, 207,5 ft, and 146,5 ft, respectively.
- 10 ft long cores were obtained for virtually the entire sequences in DUM-1 (15 cores) and DUM-3 (14 cores), and the deeper part of well DUM-1 (5 cores). Chip samples, collected over 5 ft intervals, were obtained from the strata between the cored intervals.
- Downhole video provided continuous images of the walls of each well and highlighted the presence of fractures and cavities. It should be noted, however, that cloudy water conditions in some parts of the wells obscured some of the finer details.
- Porosity and permeability values were obtained for twenty-five samples from various parts of the succession in each well.
- Wells DUM-1, DUM-2, and DUM-3 penetrated, from youngest to oldest, the Ironshore Formation, Pedro Castle Formation, Cayman Formation, and Brac Formation. No samples were collected from the Ironshore Formation because the constituent rocks are extremely friable and disintegrated during drilled.
- The Pedro Castle Formation is formed of dolostone and some limestone, the Cayman Formation is formed entirely of dolostone, whereas the Brac Formation is formed of limestone and dolostone. Fossils (mainly, corals and bivalves) are common throughout the succession. Those organisms that originally had aragonitic skeletons are now represented by fossil-moldic porosity.
- The successions in wells DUM-1, DUM-2, and DUM-3 are similar to the successions found in the surrounding area, including those around the nearby sewerage works, and wells to the south and north of the ReGen site.
- A cave was encountered in well DUM-1 at a depth of 108 to 114 ft.
- Porosity in the limestones and dolostones of the Pedro Castle Formation, Cayman Formation, and Brac Formation includes intercrystalline pores, fossil-moldic porosity, fractures, and caves/cavities of various sizes. Tested porosity values for 25 samples from all formations ranges from 10.1 to 39.7%. The range of porosity values is similar for all three formations.
- Vertical fractures are common in some parts of the succession (e.g., between 350 an 404 ft in DUM-1).
- Permeability in the limestones and dolostones of the succession in wells DUM-1, DUM-2, and DUM-3 are highly variable. Although the Kmax values are generally low, some samples are characterized by high Kmax values.

- Based on the data from the 25 tested samples from DUM-1, DIM-2, and DUM-3, there is no correlation between the porosity and permeability (Kmax), irrespective of the formation or position of the samples in each formation.
- The porosity and permeability patterns DUM-1, DUM-2, and DUM-3 are similar to those found in other wells from the surrounding area, including those around the nearby sewerage works, and wells to the south and north of the ReGen site. Such comparisons also show the geographic and stratigraphic variability in porosity and permeability patterns, at all scales, in this area.

INTRODUCTION

This report focuses on the geological succession found in subsurface of the ReGen site, which is located near the George Town Landfill (GTLF) situated just north of George Town (Fig. 1). Three wells were drilled to assess the subsurface geology of the area relative to the well-established stratigraphic succession of the Cayman Islands (Fig. 2).

Figure 1. Southwest corner of Grand Cayman showing location of drilling site (DUM), area to north and east (white box) where numerous wells have been drilled, and wells GTH-1 and GET-1.

STRATIGRAPHY

The stratigraphic succession in the upper 500 ft of strata on the Cayman Islands is divided, from oldest to youngest, into the Brac Formation, Cayman Formation, Pedro Castle Formation, and Ironshore Formation (Figs. 2, 3). Full descriptions of each formation can be found in Jones (2022). The main characteristics of each formation are as follows.

Brac Formation: This formation is poorly known on Grand Cayman because it is not exposed at the surface and has only been found in some of the deeper wells (e.g., LV#2, SHT#4). On Cayman Brac, it is exposed in the cliff faces on the east end of the island where it includes various types of limestones and dolostones. Available information indicates that it is probably Upper Oligocene in age.

Cayman Formation: This formation, widely exposed on Cayman Brac and Grand Cayman, is formed mostly of dolostones that contain a rich, diverse biota that includes corals, bivalves, and gastropods. In the central eastern part of Grand Cayman, the formation includes limestones, but these have only been found in some of the deeper wells.

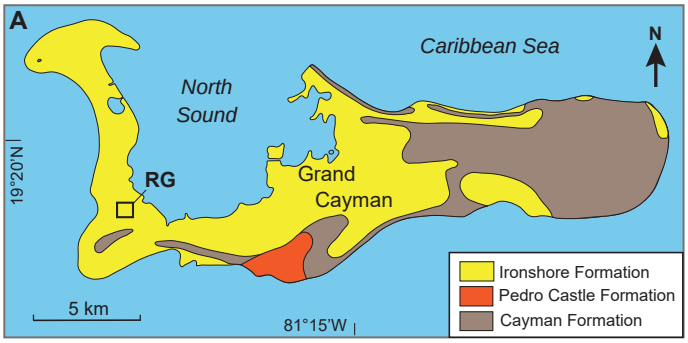

Figure 2. Map showing surface distribution of the Cayman Formation, Pedro Castle Formation, and Ironshore Formation on Gr and Cayman (modified from Jones, 1994, his Fig. 2.3A). RG indicates location of the ReGen site.

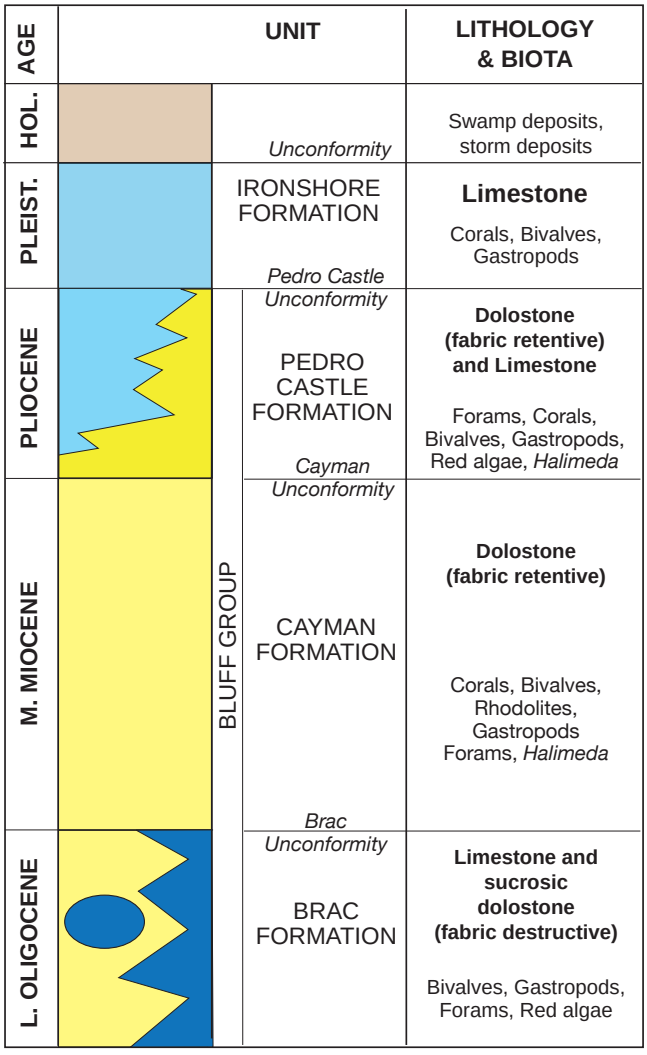

Figure 3. Stratigraphy of the Cayman Islands (modified from Jones, 1994, his Fig. 2.4).

Pedro Castle Formation: This formation, exposed on the east end of Cayman Brac, the area around Pedro Castle on Grand Cayman, and possibly some in some scattered outcrops on Little Cayman, is formed of variable amounts of limestone and dolostone that commonly contain diverse faunas of corals, bivalves, and gastropods.

Ironshore Formation: This formation, widely exposed on each of the Cayman Islands, is formed of friable limestones that typically contain numerous, well-preserved corals, bivalves, and gastropods. It is generally impossible to obtain cores from this formation.

Recognition of Critical Stratigraphic Boundaries

The four formation in the upper 500 feet of strata on the western part of Grand Cayman (Fig. 3) are separated from each other by unconformities that are characterized by high relief topographies that developed when the island was exposed to weathering during periods of sea-level lowstands. For convenience, these unconformities are referred to as the Brac Unconformity, Cayman Unconformity, and Pedro Castle Unconformity (Fig. 3). The upper boundary of the Ironshore Formation is either buried beneath modern peat deposits or exposed at the surface. Some of these unconformities are well known because they are exposed at the surface (e.g., Cayman Unconformity – exposed in Pedro Castle quarry) and/or have been documented from many wells. In contrast the Brac Unconformity on Grand Cayman is poorly understood because it has only been found in a few of the deeper wells.

The summary information in Figure 4 shows the topographies of the unconformities on an island-wide scale. It is important to note, however, that local variations in the elevations on the these unconformities are also common, but impossible to depict at the scale used in Figure 4.

Pedro Castle Unconformity

This unconformity, which separates the Pedro Castle Formation from the underlying Cayman Formation is easy to identify during drilling by the significant change in drilling rate from the poorly lithified limestones of the Ironshore Formation to the harder, better lithified limestones of the Pedro Castle Formation. On the western part of Grand Cayman it is generally impossible to obtain cores from the Ironshore Formation, whereas cores can be produced from the Pedro Castle Formation.

Cayman Unconformity

This unconformity, well-exposed in the south wall of Pedro Castle quarry, is characterized by a rugged topography with at least 100 feet of relief on it across Grand Cayman. On the western part of the island, the transition from the Pedro Castle Formation to the underlying Cayman Formation is typically marked by (1) a reduction in the drilling rate, and (2) an increase in the core recovery percentage. Cores from the Pedro Castle Formation are commonly characterized by broken core pieces and low core recovery rates, whereas the uppermost part of the Cayman Formation is generally characterized by high core recovery rates and longer core segments. In some areas, the lower part of the Pedro Castle

Formation is formed of limestones whereas the underlying Cayman Formation is formed of dolostone. Some care must be taken with this issue because the Pedro Castle Formation is, in some areas, formed of intercalated limestone and dolostone.

Brac Unconformity

Although well exposed in the cliff faces on the east end of Cayman Brac, the Brac Unconformity is difficult to characterize on Grand Cayman because (1) it is not evident in any surface exposures, and (2) it has only been identified in a few of the deeper wells drilled in the central and western part of the island. Given the paucity of good cores from the deeper wells on Grand Cayman, recognition of the Brac Unconformity has been based largely on the $^{87}Sr/^{86}Sr$ ratios of the rocks given that this ratio is known to have systematically changed during the Oligocene, Miocene, and Pliocene (Wang et al., 2019). McCormick and Jones (2021) followed a similar approach by suggesting that the sudden change in the

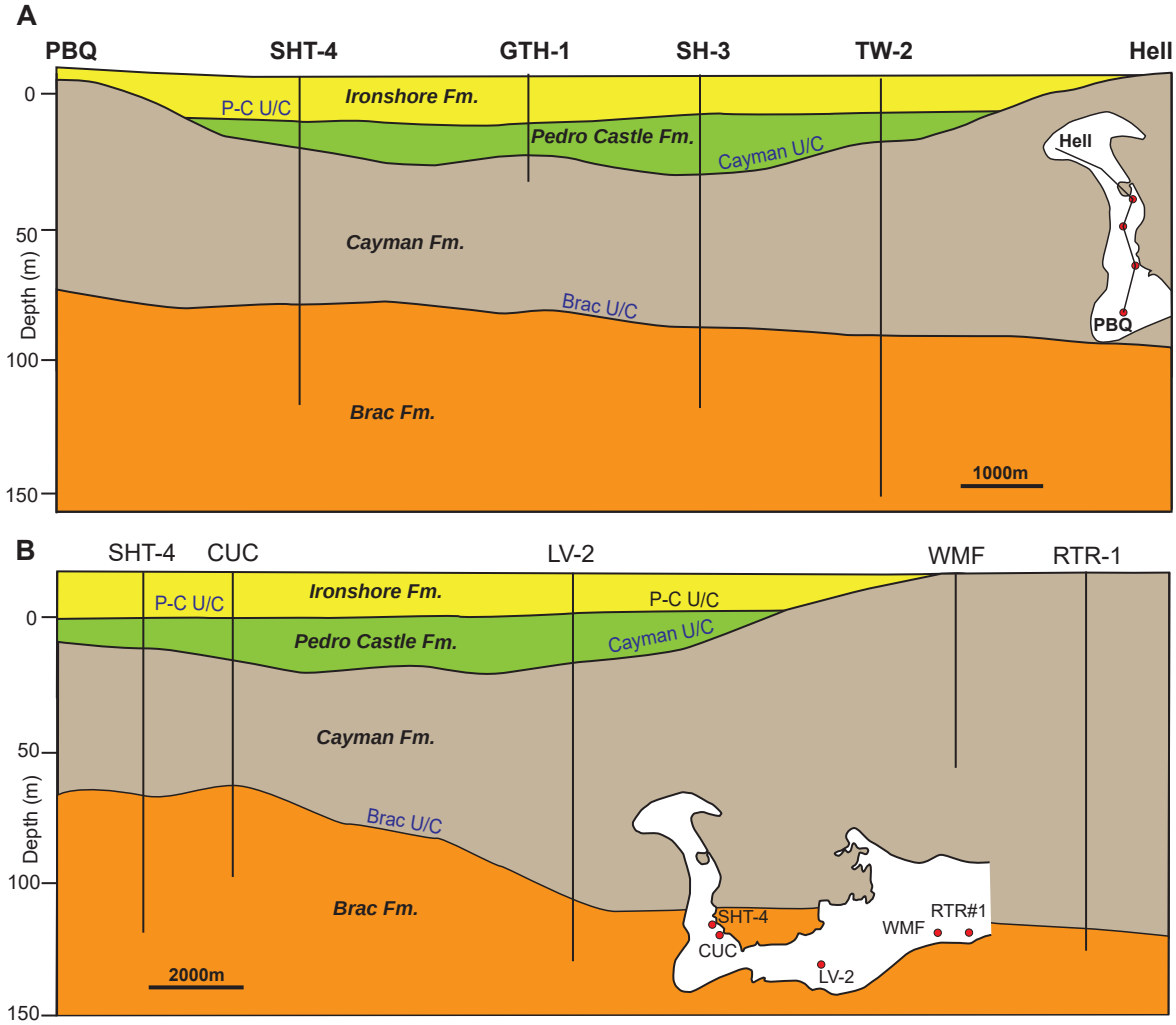

Figure 4. Stratigraphic cross-sections from (A) PBQ to Hell, and (B) SHT#4 to RTR#1 showing variations in thicknesses of the Brac Formation, Cayman Formation, Pedro Castle Formation, and Ironshore Formation and the Brac Unconformity (Brac U/C), Cayman Unconformity (Cayman U/C), and Pedro Castle Unconformity (P-C U/C) that form the boundaries between the formations. Modified from McCormick and Jones (2021, their Fig. 11).

$^{87}Sr/^{86}Sr$ ratios in these successions is an indicator of the Brac Unconformity. In well SHT#4, located ~200 m NNE of DUM-1 (Fig. 3), they placed the Brac Unconformity at a depth of 75.7 to 80.6 m (248.3 to 264.4 ft) based on (1) a sudden change in the $^{7}Sr/^{86}Sr$ ratios, and (2) the presence of a 1 cm thick layer of terra rossa in the core from that interval. They also used the "break" in the $^{7}Sr/^{86}Sr$ ratios to map the position of the Brac Unconformity on the western peninsula of Grand Cayman (Fig. 4A) and in a west-east direction along the southern part of Grand Cayman. In contrast to the relatively minor relief on the Brac Unconformity on the western peninsula, McCormick and Jones, 2021) showed that there is significant relief on the unconformity along the south coast (Fig. 4B). In well LV#2, for example, the unconformity is at a depth of 123 m (403.4 ft), whereas in well RTR#1 it is at 129 m (423 ft). Although it is evident that the Brac Unconformity is characterized by significant relief, it must be stressed that it is impossible to produce a detailed, island-wide map of the relief because this unconformity has only been found in the deeper wells.

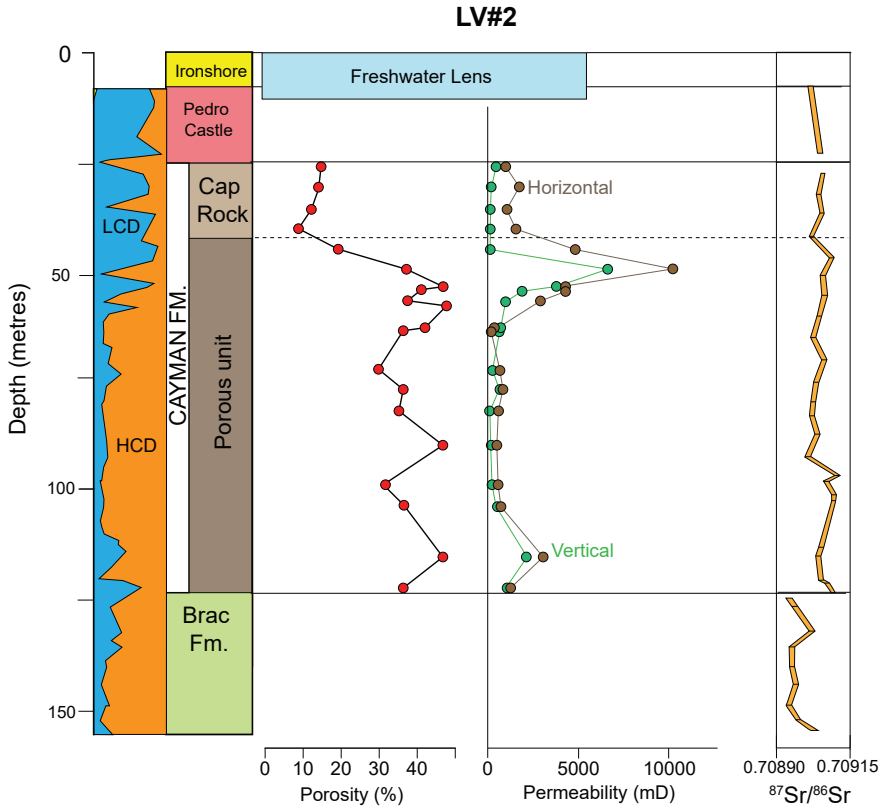

Figure 5. Succession in well LV-2 (Lower Valley) showing stratigraphic succession, porosity, permeability, and $^{87}Sr/^{86}Sr$ ratios. Note position of freshwater lens, "cap rock" at top of the Cayman Formation, and distinct break in the $^{87}Sr/^{86}Sr$ profile at the boundary between the Brac Formation and Cayman Formation. Modified from Jones (2022, Fig. 4.15).

Reference section

Well LV#2, drilled on the Water Authority site in Lower Valley in 1993, is used as a reference section because (1) it is one of the rare wells on Grand Cayman that includes the complete succession from the Brac Formation to the Ironshore Formation, and (2) it has been well documented in terms of its lithology, porosity, permeability, and $^{87}Sr/^{86}Sr$ ratios (Fig. 5) and many other geochemical attributes. Critical aspects of the succession in this well include (1) delineation of the "cap rock" at the top of the Cayman Formation,

Figure 6
West wall in Pedro Castle Quarry showing Cayman Unconformity that separates the Pedro Castle Formation (PCF) from the Cayman Formation (CF). Quarry wall is ~ 20 ft high with unconformity ~ 15 ft above sea level. The position of the unconformity is highlighted by the contrast in weathering colours.

and (2) the break in the $^{87}Sr/^{86}Sr$ ratios at the boundary between the Brac Formation and Cayman Formation. The lack of core from Brac Formation, prior to this study, meant that no porosity or permeability values are known for that part of the succession.

The "cap rock" at the top of the Cayman Formation is an informally designated dolostone unit at the top of the Cayman Formation that is characterized by low porosity and low permeability values that contrast with the high porosity and permeability values that characterize the underlying "porous unit" (Fig. 5). Parts of the "porous unit" are also characterized by high permeabilities (Fig. 5). The drilling rates through the cap rock were slower than those through the underlying "porous unit". It is important to note, however, that the cap rock is not recognizable in every well that has been drilled through the Cayman Formation. On the eastern part of the island, for example, it is rarely apparent. Similarly, it is not always evident in wells drilled on the western part of the island. Where present, it is commonly of different thickness to that in well LV#2. This variance in the development of the "cap rock" reflects the fact that its presence reflects diagenetic processes that (1) transformed the original limestones to dolostone, and (2) controlled the development of porosity and permeability in these rocks. Despite an extensive database, it has been impossible

to identifiable pattern to the presence/absence of the cap rock and the degree to which it developed across the island. It is critical to recognize that this hard, low-porosity and low permeability unit is not present at all locations.

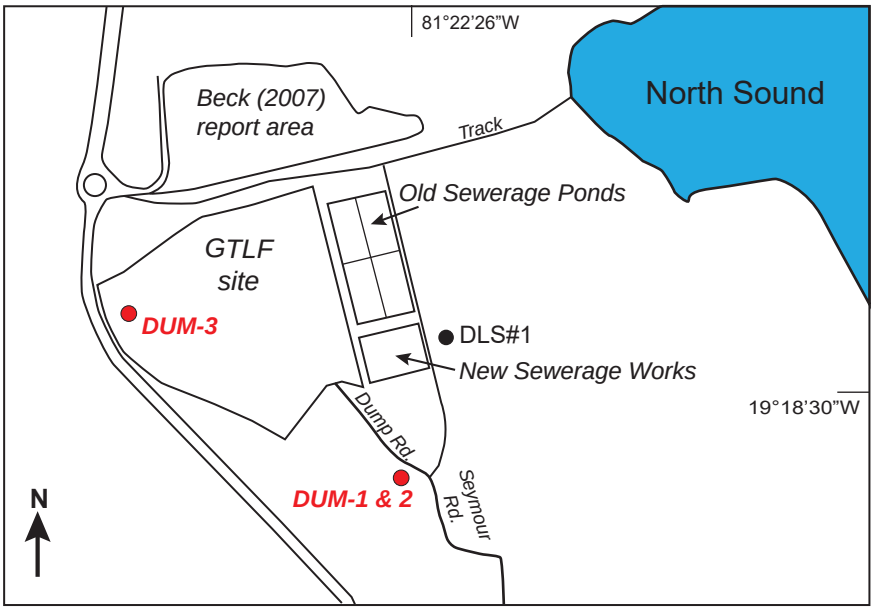

Figure 7
Map showing location of wells DUM-1, DUM-2, and DUM-3 relative to the area mapped by Beck (2007), the Old Sewerage Works, the New Sewerage Works, and well DLS#1.

METHODS

Three wells (DUM-1, DUM-2, DUM-3) were drilled on the Regen site by Brewster Well Drilling, during early December 2022 (Fig. 4). Each core, 4 inches (~10 cm) in diameter, was cut using a 10 foot (~3 m) core barrel.

(1) Well DUM-1 was drilled to a depth of 407.25 ft with (1) no samples from the upper 30 ft that penetrated the poorly lithified Ironshore Formation, (2) five 10 ft cores from 250-260 ft, 310-320 ft, 338.5-346 ft, 372.5-382 ft, and 397.5-407 ft and (3) cutting samples were collected from the upper part of the well and between the cores (Fig. 9). Each sample of cuttings were collected from 5 feet thick intervals (Fig. 9).

(2) Well DUM-2, located ~ 6 m from DUM-1 and drilled to a depth of 207.5 ft. Coring started at 31 ft, with essentially continuous coring to a depth of 170 ft (14 ten-foot cores), (2) chip samples were collected between 170 to 200 ft, and (3) one core from 200 to 210 ft (Fig. 9). Each sample of cuttings were collected from 5 feet thick intervals (Fig. 5). This well was drilled because a large cavity at 108-113 ft in well DUM-1 caused problems with drilling and water circulation.

(3) Well DUM-3, located ~650 m to northwest of DUM-1 and DUM-2, on the outer edge of the GTLF site, was drilled to a depth of 146.5 ft. No cores were obtained from the upper 28 ft of the well that penetrated through the Ironshore Formation. Fourteen cores (up to 10 ft long) were obtained between 28 ft and the base of the well at 146.5 ft (Fig. 9).

While in the field, each segment of core was sequentially numbered from the top down (e.g., C1-1, meaning core #1, segment #1, top), labelled with an arrow that indicate the "way-up" of the core, and

carefully packed in a core box. Well cuttings were placed in plastic sample bags that were carefully labelled with their depth intervals. While in the field, after labelling, photographs were taken of all core. Photographs of all the core from the wells DUM-1, DUM-2, and DUM-3, are provided in Appendices 1, 2, and 3, respectively. Photographs of the chip samples from DUM-1, below a depth of 250 ft were also taken. The chip samples were tested with 10% HCl in order to determine if they are formed of calcite or dolomite.

Rock Competence

Rock competence is used to describe the overall "strength and resistance" of a rock. Although impossible to measure precisely, the hardness of the rock are herein assessed, on a relative basis, from the drilling rates, Core Recovery (CR) percentage, and the Rock Quality Designation (RQD). These data must be interpreted with caution because other factors related to the drilling process may influence these parameters. It is important to note that the values determined for the cores from wells DUM-1, DUM-2, and DUM-3 should not be compared directly with those values determined from other wells that were drilled and cored using different drilling systems.

Drilling Rates: This is based on the premise that the rate of drilling will primarily be a function of the "hardness" or "competency" of the rock. Although simple in principle, this parameter is also controlled by other factors, including the type of drill bit used, the age and degree of wear of the drill bit, drilling speed, and/or the downhole weight on the drill bit. Core drilling is typically slower than the drilling rates associated with the collection of well cuttings. Despite these issues, the rates of drilling can provide valuable insights regarding the hardness of the rock.

Core Recovery: This parameter provides a measure of the length of hard, competent rock relative to the amount of cavity space for a specified core run length. In theory, the length of retrieved core plus the cumulative lengths of bit drops should equal the total core run length. When drilling through poorly lithified rock, however, disintegration of the bedrock may occur and no core will be obtained. This is the reason, for example, why no core was obtained from the Ironshore Formation.

Rock Quality Designation: This term, introduced by Deere (1967), is based on the total length of core pieces that are each longer than 4 inches (10 cm) relative to the length of the core run. It can be used as a measure of the "good" rock in a borehole (Deere and Deere, 1988). This index is, however, sensitive to the length of the core run. Thus, comparisons of the RQD should be based on core run lengths that are, or close to being, the same.

Downhole video

Following drilling of wells DUM-1 and DUM-2, a GeoVISION Dual Scan Micro Camera system was lowered down each well in order to obtain a continuous visual video record of the walls of each well. These videos provides coverage of those parts of the well that were not cored or intervals for which core recovery was poor.

As the video camera was lowered down the hole, it was stopped at various depths so that it could obtain a 360° panoramic view of the borehole. These video images are particularly useful because they show the (1) general nature of the intervals for which core were not obtained, and (2) the presence of fractures that may not be evident from the core - this is especially true for the larger fractures. It is, however, impossible to determine if the rock is limestone or dolostone from the video images.

Problems were encountered with the acquisition of the downhole videos because of the substantial amounts of very-fine grained sediment that was present in parts of the wells. In many areas, this sediment lined the smaller pores and lay on the floor of the larger cavities. Disturbance of this sediment during drilling meant that the water in the wells commonly remained turbid for long periods of time after the drilling was completed.

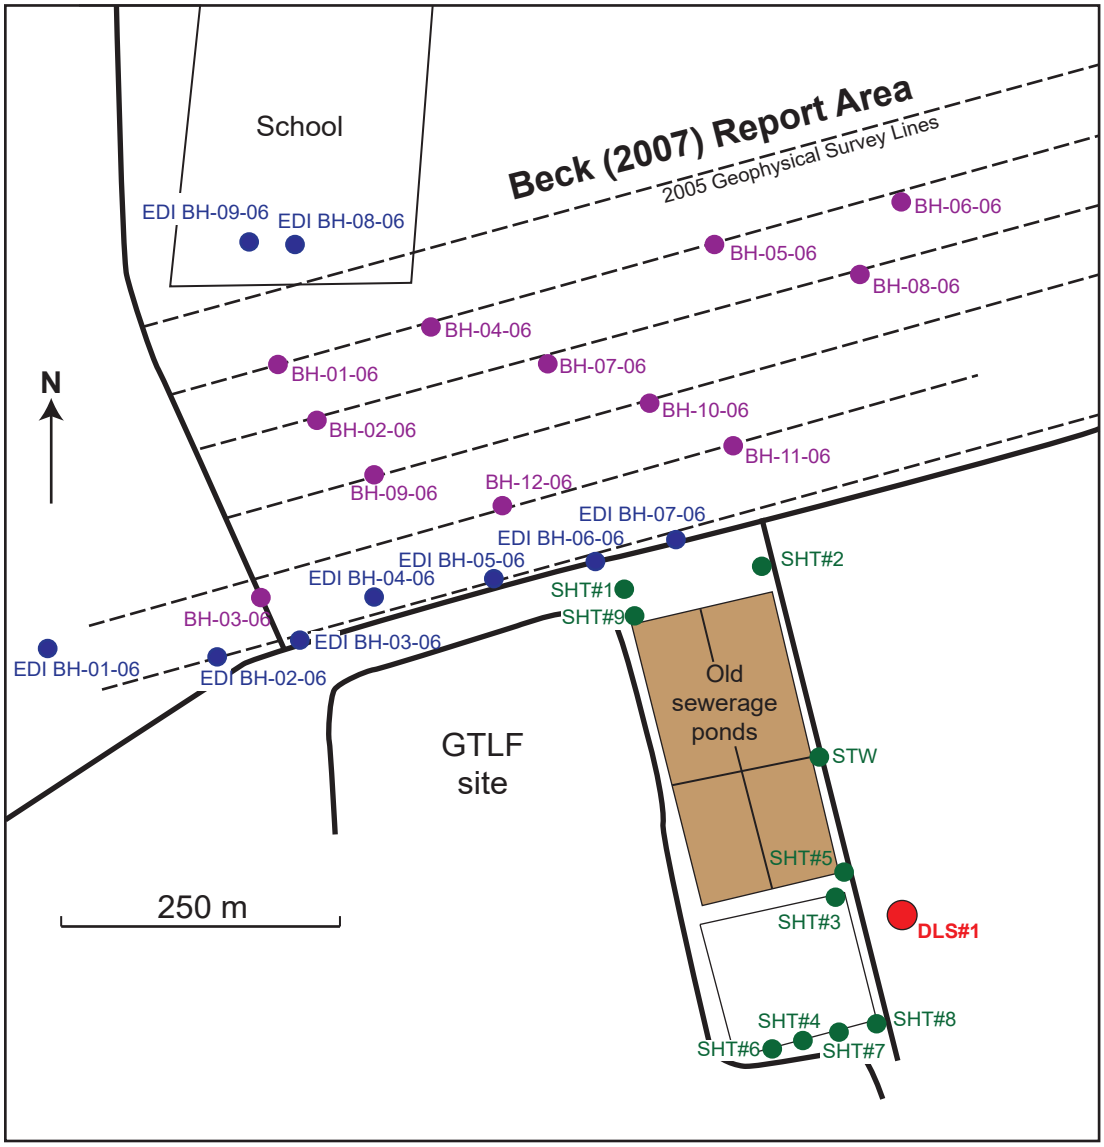

Figure 8: Location of wells that have been drilled in areas around the GTLF site. See text for listing of the origin of these wells.

Given that DUM-1 and DUM-2 were drilled very close to each other (~20 ft apart). Continuous coring to a depth of 170 ft in DUM-1 provides a continuous record of the rock succession. Accordingly, the downhole video for this succession focuses on the succession in DUM-1 between 170 and 407.25 ft.

WELLS DRILLED AROUND DUM WELLS

Data obtained from wells DUM-1, DUM-2, and DUM-3 are assessed relative to numerous wells that have been drilled to the east and north of the GTLF site (Figs. 6, 7) that includes the following:

1. **North of GTLF site**: Beck (2007) provided a detailed report that covered 12 wells that were drilled and cored to a maximum depth of about 130 ft using a wire-line drilling system. These wells penetrated the Ironshore Formation, Pedro Castle Formation, and the upper part of the Cayman Formation. His report provided images of all of the cores that are now held in storage by Dart.

2. **North of GTLF site and school site:** Environmental Diagnostics Inc (EDI) drilled two wells on the site where the school is now built and 7 wells on the north side of the east-west track at the north end of the area that encompasses the GTLF site and the old sewerage work site (Fig. 4). These wells, drilled to a maximum depth of about 130 ft, penetrated the Ironshore Formation, Pedro Castle Formation, and the upper part of the Cayman Formation. The report on these wells included photographs of all of the core. The location of these core today is unknown.

3. **Old Sewerage Works:** A research group, led by Dr. Brian Jones (University of Alberta) drilled and cored 6 wells (SHT#1 to 5 and 9) around the north and east margins of the old sewerage ponds (Fig. 4). Core from these wells, that were drilled to a maximum depth of 130 feet, penetrated the Ironshore Formation, Pedro Castle Formation, and the Cayman Formation. Information from these cores has been included in various theses and papers. The core from these wells is stored at the University of Alberta.

4. **New Sewerage Works:** The Water Authority drilled four wells along the southern boundary of the Water Authority site (to south of new processing plant). These wells (SHT#4, SHT#6, SHT#7, and SHT#8) included SHT#4 that reached a depth of 480 feet. The well cuttings and core obtained from SHT#4 well are stored at the University of Alberta. No core or cutting samples were collected from the other wells. These wells penetrated the Ironshore Formation, Pedro Castle Formation, and Cayman Formation. The lower part of well SHT#4 penetrated the Brac Formation.

5. **Laundry well:** This well (DLS#1-Fig. 8), drilled in 2020 by Industrial Services and Equipment Ltd., reached a depth of 200 ft. Cores and well cuttings were obtained from this well. The report on this well (Jones, 2020) included photographs of the core.

Integration of information from the wells in these five areas, which has involved analyses of the core, well cuttings, and tested porosity and permeability values means that there is a good understanding of the subsurface geology of the area. This information is also assessed relative to information derived from well GTH-1 drilled to the north, GET#1 (Fig. 1) that was drilled to the south, and LV#2 drilled to the east of the DUM site, four wells drilled at the Cayman Utilities site, and 4 wells drilled at the Red Gate site (Water Authority) to the east has been well established and provides a model for assessing the subsurface geology

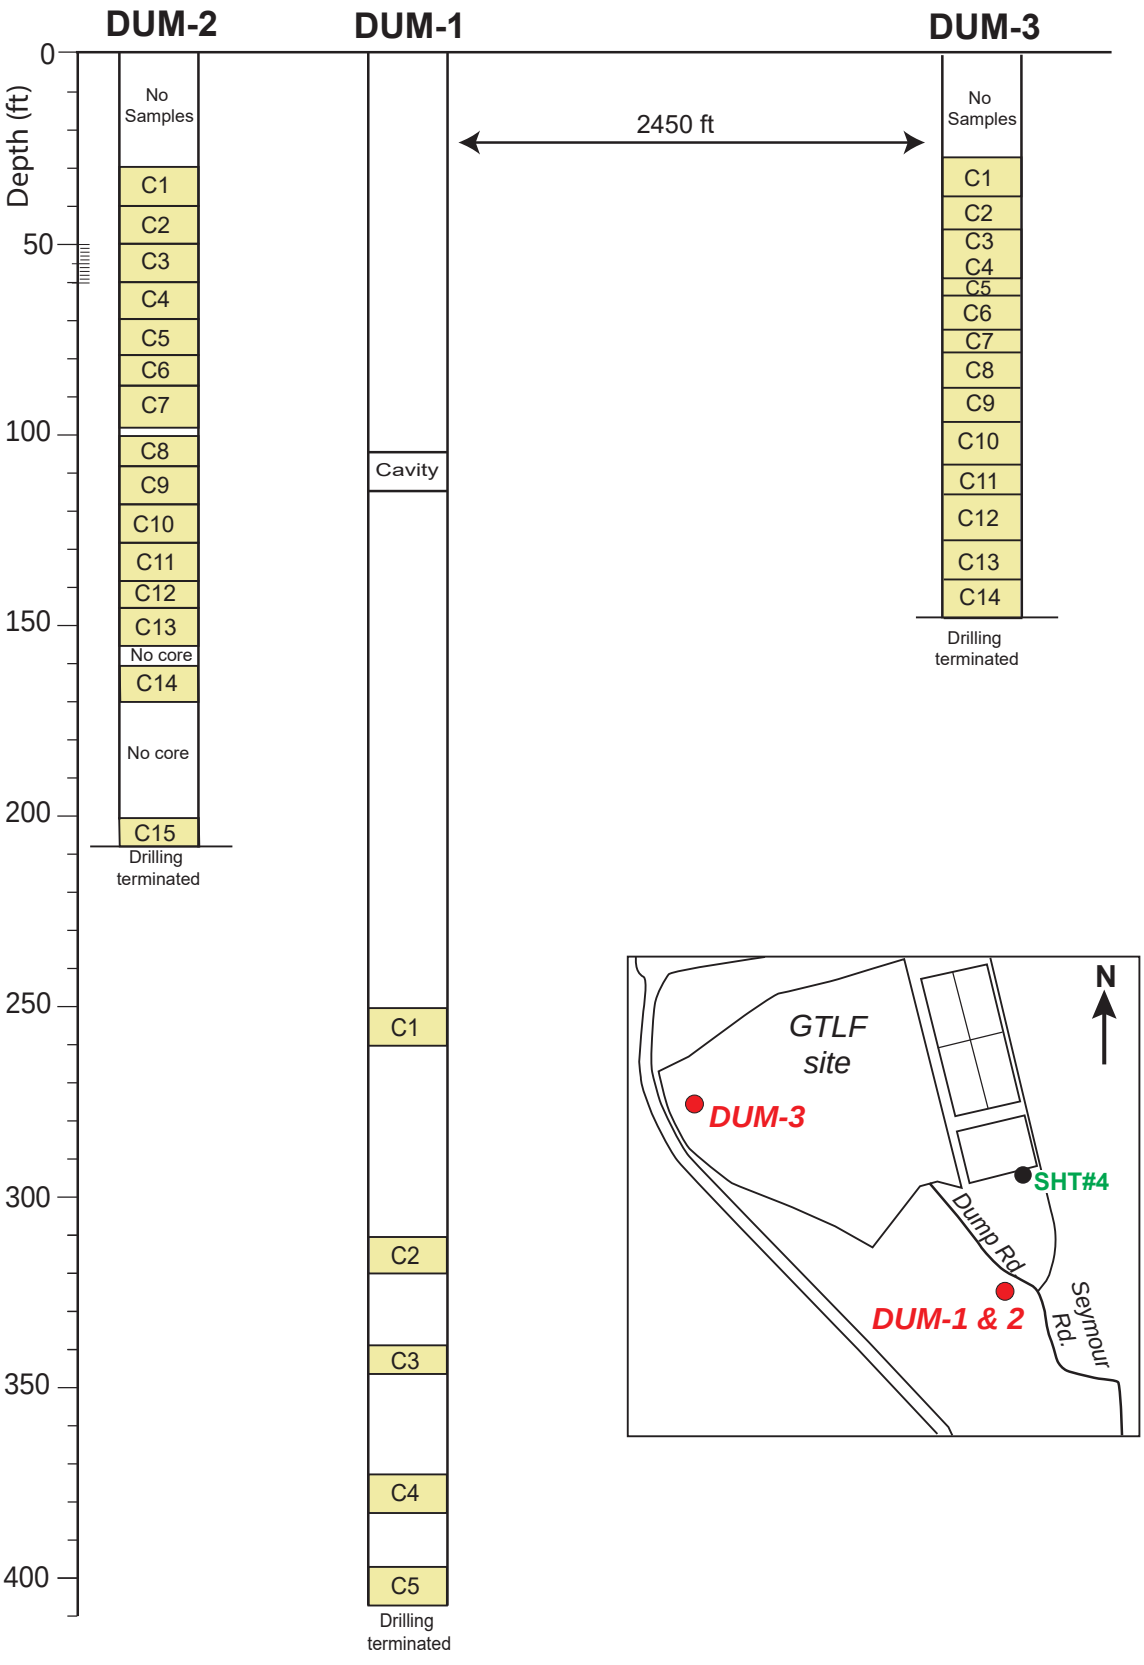

Figure 9: Location of cores cut in wells DUM-1, DUM-2, and DUM-3. Cuttings collected over 5 ft intervals between cores. DUM-1 and DUM-2 are adjacent to each other (< 20 ft apart).

penetrated by wells DUM-1, DUM-2 and DUM-3. It is important to note, however, that most of the wells in these areas are less than 200 feet deep with only SHT#4 (480 ft) being deeper. As a result, the upper 200 feet of strata are well documented from many perspectives, whereas information for those strata below 200 ft is available only from well SHT#4.

WELLS DUM-1, DUM-2 AND DUM-3

The area that encompasses wells DUM-1, DUM-2, and DUM-3 is located north of Georgetown on the southwest corner of Grand Cayman (Fig. 1). Wells DUM-1 and DUM-2 were only ~ 20 ft apart. The sequences evident in these wells must be considered relative to the succession in well LV-2 that is located on the Water Authority site, Lower Valley (Fig. 2) and various wells in the area around the GTLF site (Fig. 3). Well SHT#4 is particularly important in this respect because it includes a complete succession like that in well LV#2.

Rock Competence

The drilling rates for all three wells were rapid with little downhole variance (Figs. 9, 10). Significant variance in these rates was only encountered when different drill bits were used. There are no obvious reasons for the rare slower rates of drilling core in some parts of the successions (Figs. 9, 10).

Core recovery was excellent in all three wells with core recovery commonly in the 80 to 100% range (Figs. 10, 11). The reason for the variable core recovery percentage from the Cayman Formation in DUM-2 is not readily apparent (Fig. 9). This variability, however, was not evident in the DUM-3 well (Fig. 10). The RQD was high throughout all of the drilling with very few core pieces being < 4 in (10 cm) long (Figs. 10, 11). In wells DUM-2 and DUM-3 some intervals of rubble formed through the breakdown of the core are present (see Appendices 2 and 3).

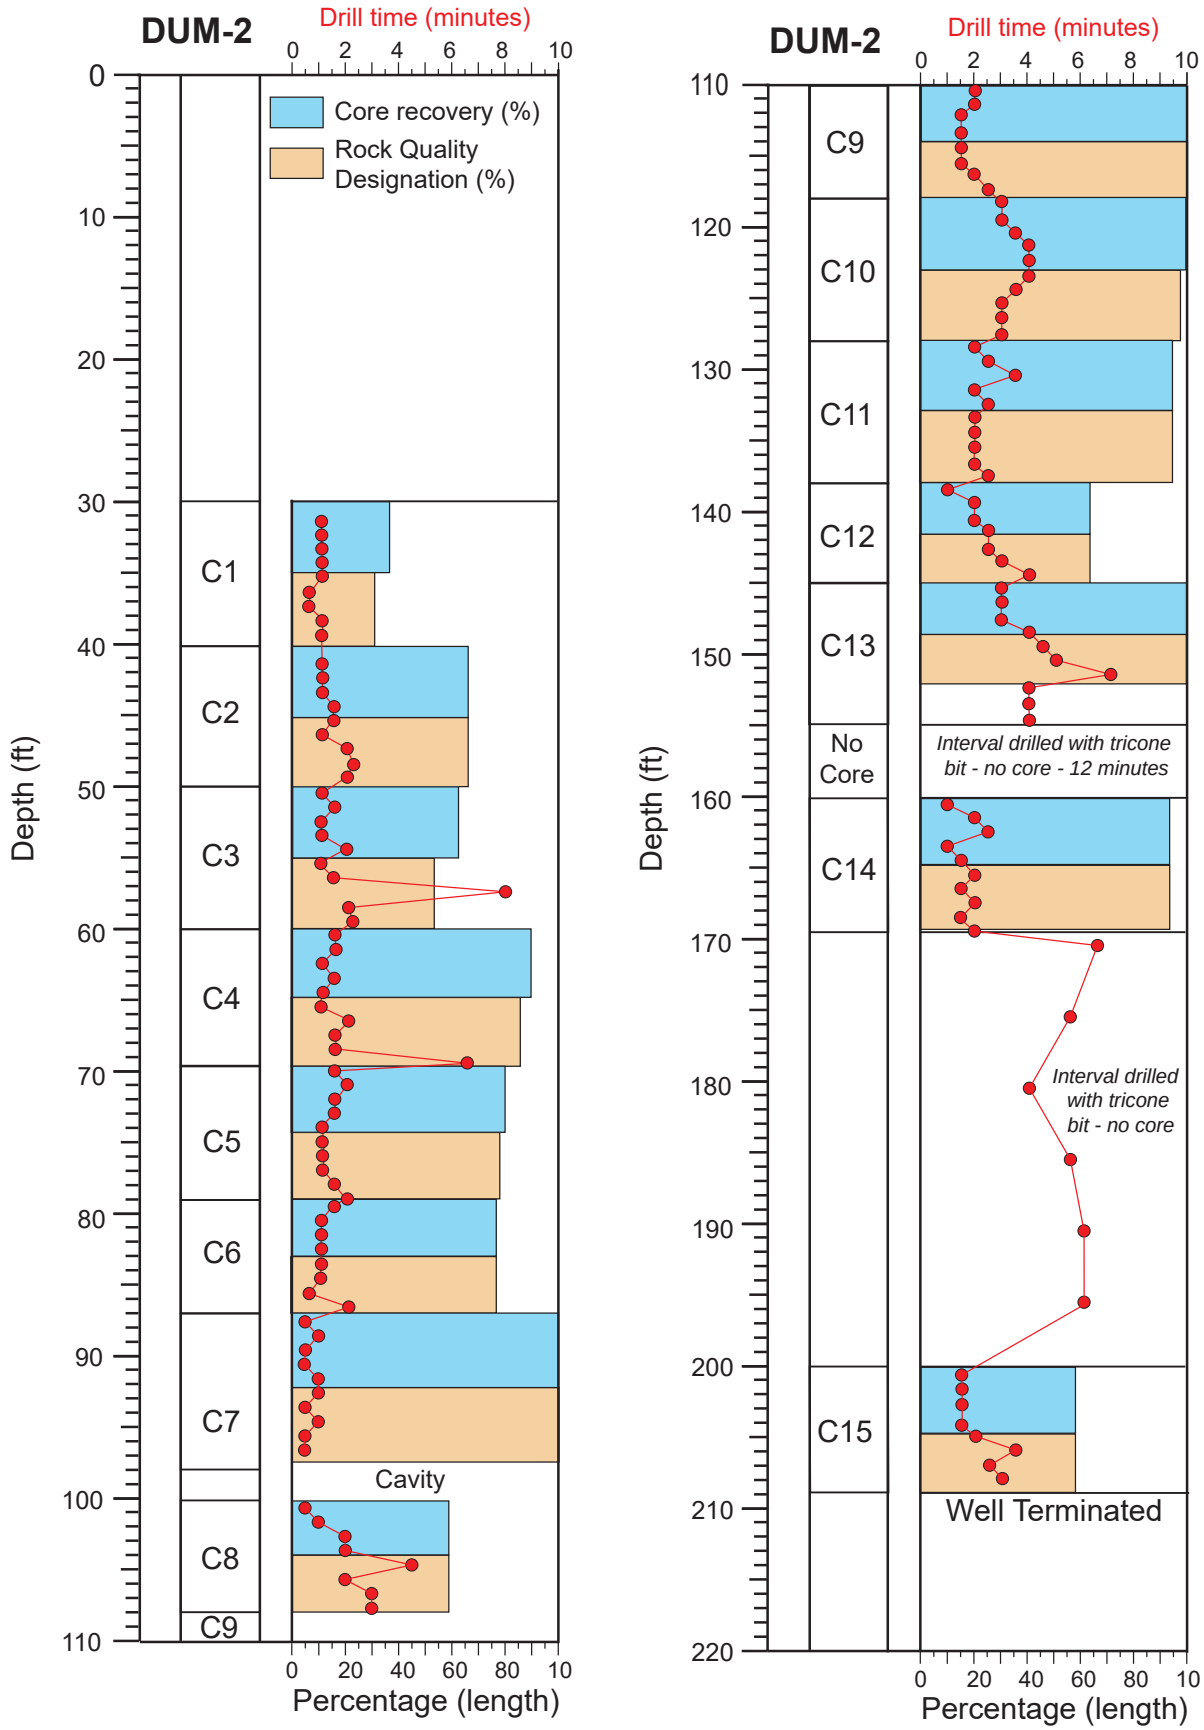
No core was recovered from the Ironshore Formation because the limestones in that formation are extremely friable and disintegrate during drilling.

Formation Boundaries in DUM-1, DUM-2, and DUM-3

The boundaries between the formations are marked by the Pedro Castle Unconformity, the Cayman Unconformity, and the Brac Unconformity (Figs. 3, 4), with each being characterized by significant topographic variability (Fig. 4). In wells DUM-1 and DUM-2 and DUM-3, these unconformities are located at variable depths (Figs. 10, 11).

Pedro Castle Unconformity

The top of the Pedro Castle Formation is placed at the depth where resistance to drilling was first encountered and coring of the bedrock became possible. In DUM-1and DUM-2 this was at a depth of 30 ft, whereas in DUM-3 it was at a depth of 28.5 ft. This variation in the depth to the top of the Pedro Castle Formation is similar to that found throughout the surrounding area.



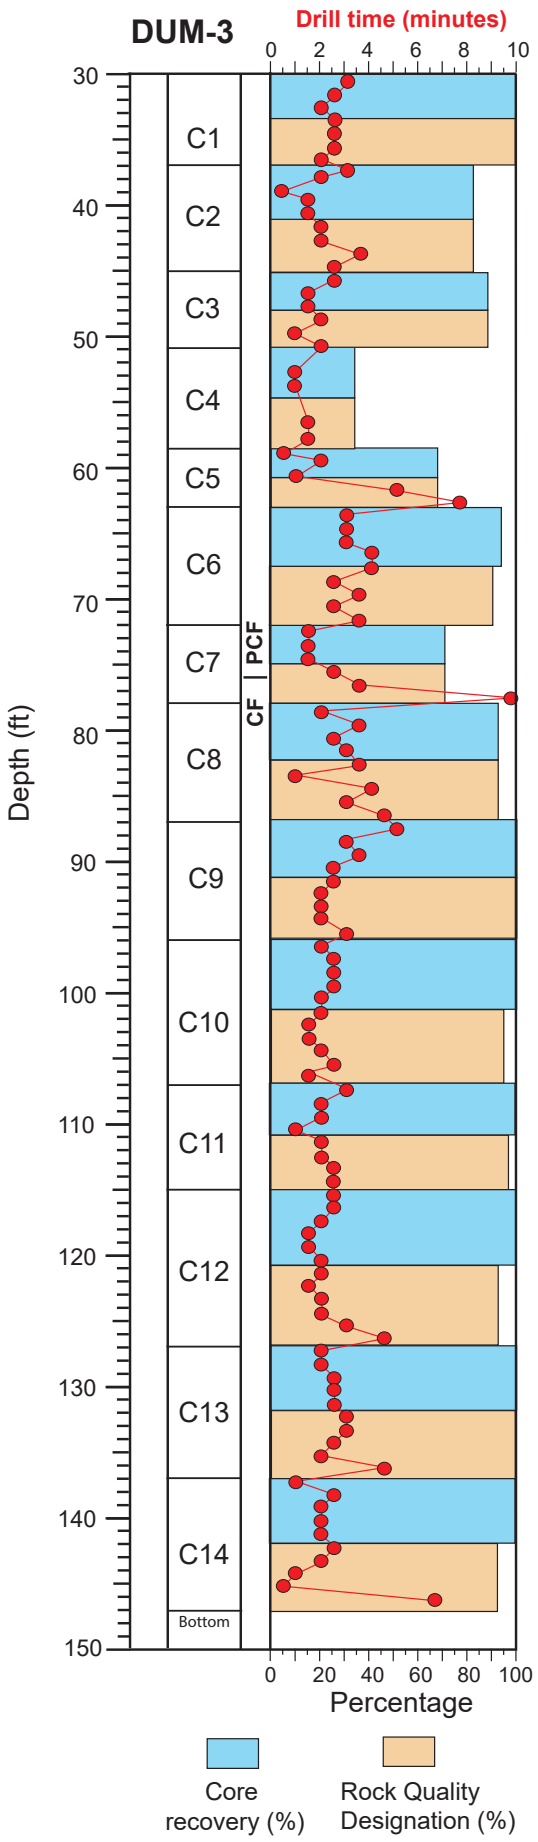


Figure 10: Well DUM-2 – location of cores C1 to C15, drill times, and percent core recovery, and rock quality designation (RQD).

Cayman Unconformity

The Cayman Unconformity is generally easy to recognize and locate in surface outcrops because of the difference in the weathered colours of the Cayman Formation and Pedro Castle Formation (Fig. 6). In the subsurface, however, it is commonly difficult to accurately place this boundary because weathered colours are not evident. Accordingly, it has commonly been placed where there there are changes in lithology, various geochemical parameters, the rate of drilling, and/or the core recovery percentage and RQD. Such parameters are commonly difficult to apply because the uppermost part of the Cayman Formation and lowermost part of the Pedro Castle Formation can both be formed of dolostone, the necessary geochemical parameters are lacking, and the rate of drilling and length of core pieces is largely a function of the drilling rig that was used.

In the following discussion it is important to note that there is a 3 ft difference between the depths determined during drilling (measured from drill table that is 3 ft above ground level) as opposed to that associated with the downhole video (measured from ground level.

In DUM-2, the boundary is probably located at a depth of about 76 ft. Between 30 and 76 ft, the core is generally broken into small lengths and characterized by numerous small cavities (Appendix 1). Careful inspection of the downhole video shows that the wall of the well between 30 to 76 ft is dark grey in colour and highly irregular with numerous small cavities (Fig. 12A, B). In contrast, the wall of the well below 76 ft is smooth and light grey to beige in colour (Fig. 12C, D).

For DUM-3, there are similar contrasts in the nature of

Figure 11

Well DUM-3 – location of cores C1 to C14, drill times, and percent core recovery, and rock quality designation (RQD). The boundary between the Pedro Castle Formation (PCF) and Cayman Formation (CF) is derived from the downhole video and core.

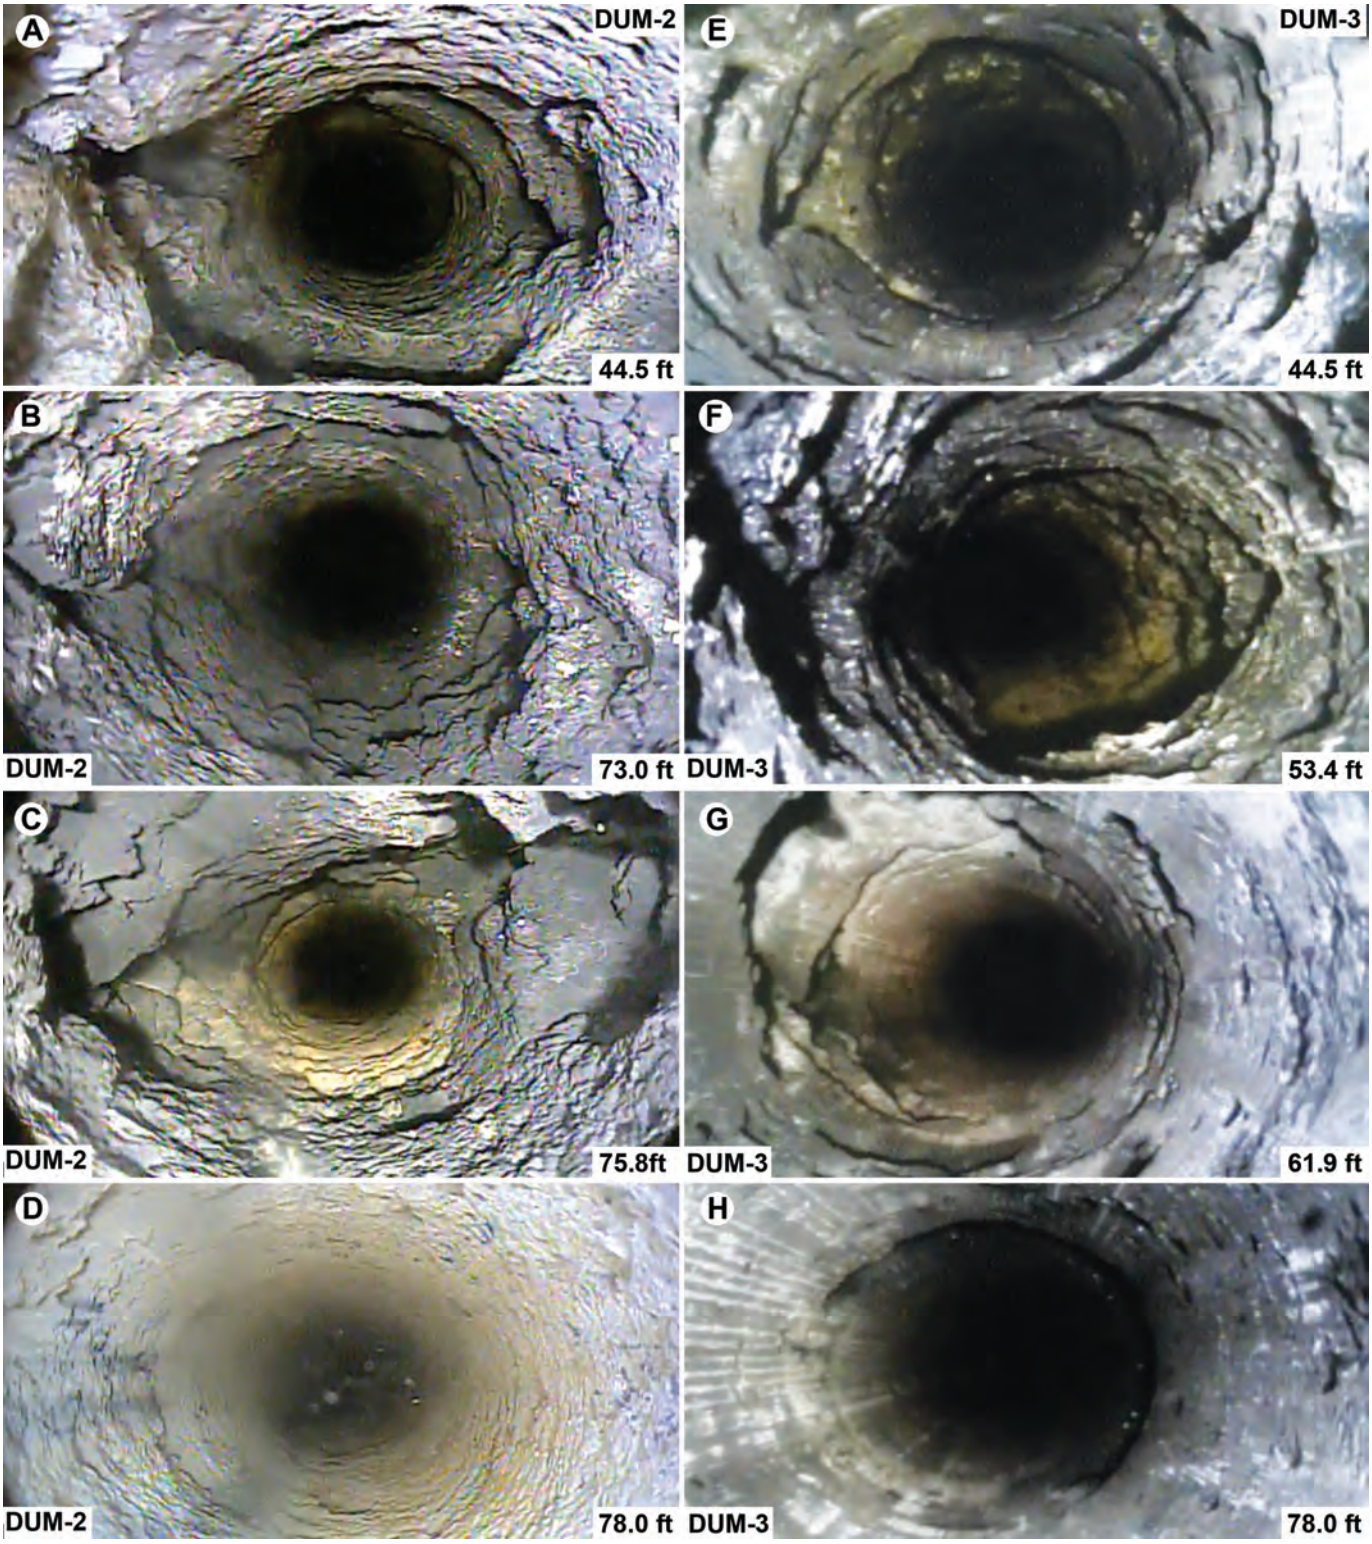

Figure 12

Location of Cayman Unconformity in DUM-2 (A-D) and DUM-3 (E-H) as identified from downhole video.

DUM-2: (A, B) Upper part of borehole characterized by uneven walls and dark-coloured rock. **(C)** Transition from Pedro Castle Formation to Cayman Formation highlighted by change in colour. **(D)** Cayman Formation, characterized by smooth walls and light coloured rock.

DUM-3: (E, F) Pedro Castle Formation with uneven walls. **(G)** Possible transition from Pedro Castle Formation to Cayman Formation. **(H)** Smooth walls of Cayman Formation.

Figure 13: Comparison of cores from the Pedro Castle Formation C1 and C2) and cores from the Cayman Formation (C5-7) from DUM-2. Note higher porosity and shorter core pieces from the Pedro Castle Formation relative to the Cayman Formation. Core diameter is 4 in (10 cm).

the core and well wall above and below ~73 ft (Fig. 12 E-H; Appendix) that probably denotes the position of the boundary between the Pedro Castle Formation and Cayman Formation.

It should be noted that there are no significant changes in the drilling rates, core recovery percentages, or RQD associated with the positions of the Cayman Unconformity in DUM-2 or DUM-3 (Figs. 10, 11).

Brac Unconformity

Recognition of the Brac Unconformity on Grand Cayman is difficult because it occurs at depths from which little core has ever been attained. Similarly, the position of the Brac Unconformity around the GTLF site is largely unknown because of the paucity of deep wells in the area. In well SHT#4, located ~200 m northeast of DUM-1, McCormick and Jones (2021) placed the Brac Unconformity at a depth of ~ 260 ft based on detailed analyses of the well cuttings, the presence of a thin layer of terra rossa, and a significant change in the $^{87}Sr/^{86}Sr$ ratios (Fig. 4A).

The position of the Brac Unconformity in DUM-1 is impossible to place accurately because of the wide spacing of the cores from that part of the succession. Core 1 (250.5-260.5 ft) is formed of finely crystalline, largely featureless dolostones (no reaction with 10% HCl acid) that probably belong to the Cayman Formation. In contrast, cores 2 (310-320 ft), 3 (338.5-346.5 ft), 4 (372.5-382.5 ft), and 5 (397.5-407.5 ft) are formed of darker coloured limestones/dolostones that are characterized by high porosity (core 2 - Fig. 12), fossil-mouldic prosity, and corals (core 3 - Fig. 12) probably belong to the Brac Formation. It is difficult, however, to pinpoint the exact location of the boundary between the Brac Formation and Cayman Formation between cores 1 and 2 (depth between 260.5 and 310 ft) in this well. Careful inspection of the downhole video from this part of the part of the well (Fig. 15) failed to identify any distinct change in the nature of the bedrock that could be attributed to the Brac Unconformity. It should be noted, however, that this unconformity can also be difficult to pinpoint in the cliffs at the east end of Cayman Brac where it was originally recognized and documented.

Between 210 ft and 406 ft in well DUM-1, there are some contrasts in the well cuttings in terms of their colour, general appearance, and reaction with 10% HCl (Fig. 16). There are, however, no systematic variations in these attributes that could be directly linked to the change from the basal part of the Cayman Formation to the upper part of the Brac Formation.

The Brac Unconformity in well DUM-1 is probably located at a similar depth to that in well SHT#4 , which is located ~ 200 m from DUM-1. Nevertheless, it must be remembered that the relief on this unconformity can be significant in some areas on Grand Cayman and on the east end of Cayman Brac (Fig. 4).

POROSITY AND PERMEABILITY

In general, the limestones and dolostones in the Pedro Castle Formation, Cayman Formation, and Brac Formation of the Cayman Islands are characterized by heterogeneous porosity and permeability patterns that are difficult to predict in any precise manner. This situation arises because the many different types of porosity and permeability developed through many different processes during their long diagenetic history.

Analysis of the Pedro Castle Formation, Cayman Formation, and Brac Formation in wells DUM-1,

Figure 14: Comparison of cores from the Cayman Formation (dolostone) and the Brac Formation (C2-310 ft and core C3-339.0 ft). Note presence of fossils (corals) in the cores from the Brac Formation. All core from well DUM-1. Core diameter is 4 in (10 cm).

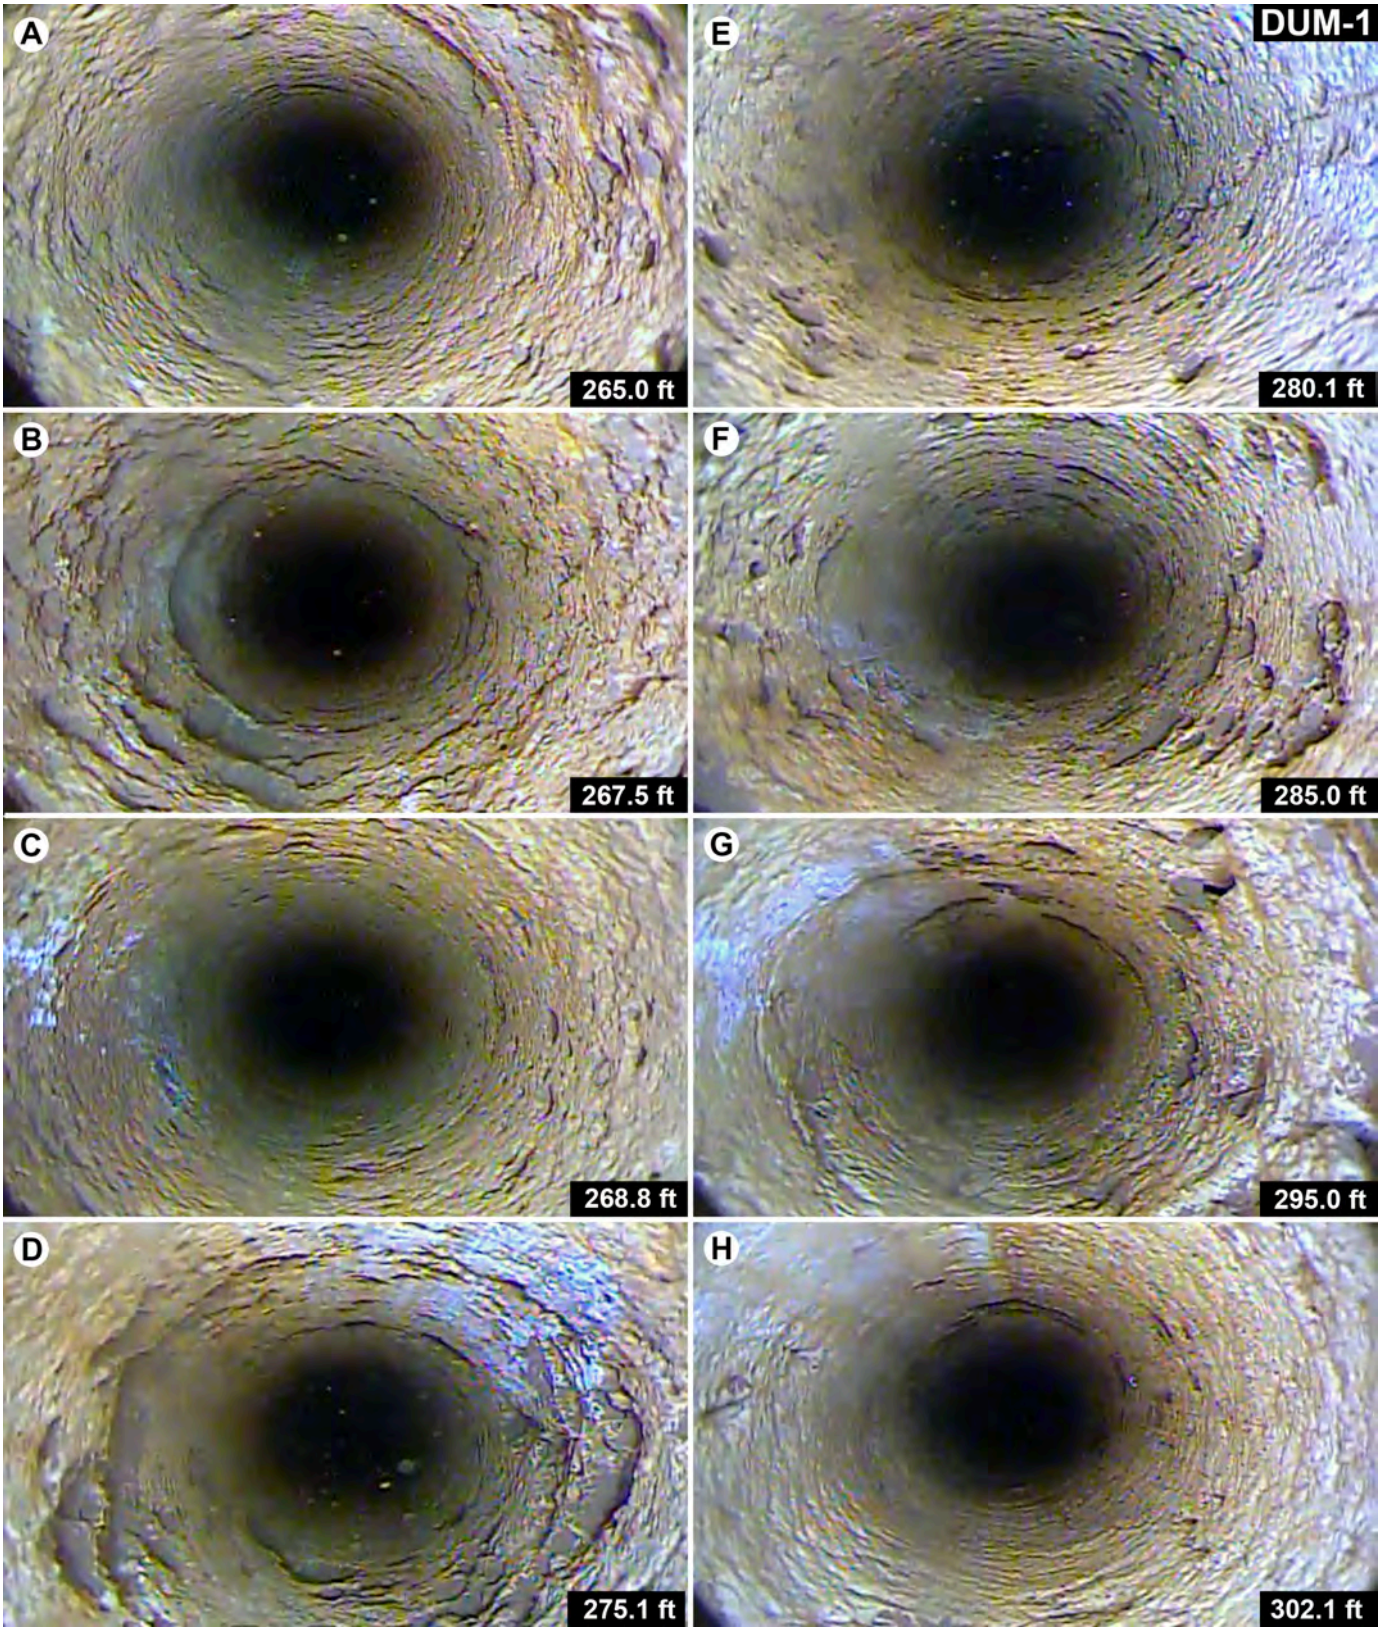

Figure 15: Downhole views of well between 265 ft and 302.1 ft showing appearance of the walls. These images cover the section of the well between core 1 (251-260 ft) that came from the Cayman Formation and core 2 (310-320 ft) that came from the Brac Formation. The exact position of the boundary between the two formations is not evident in the walls of the well. Although the exact diameter of the open borehole is unknown, the extracted core is 4 in (10 cm) in diameter.

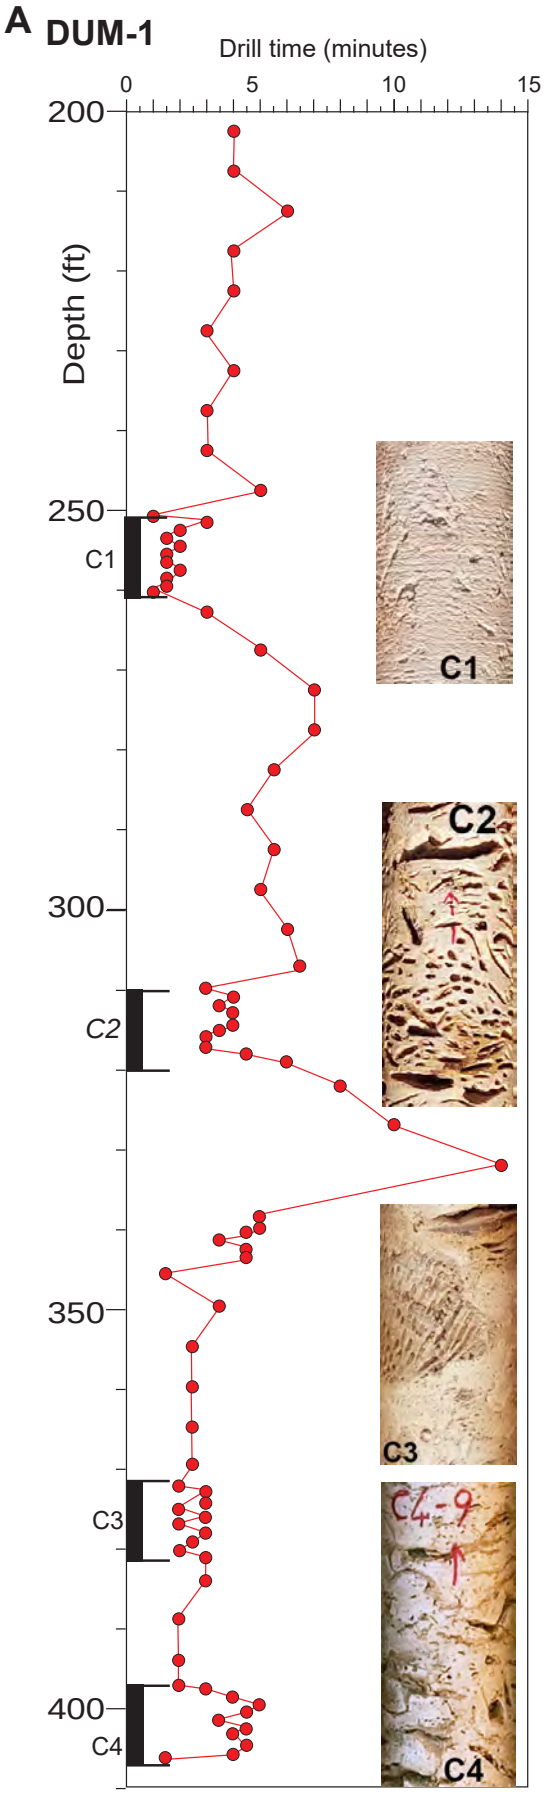

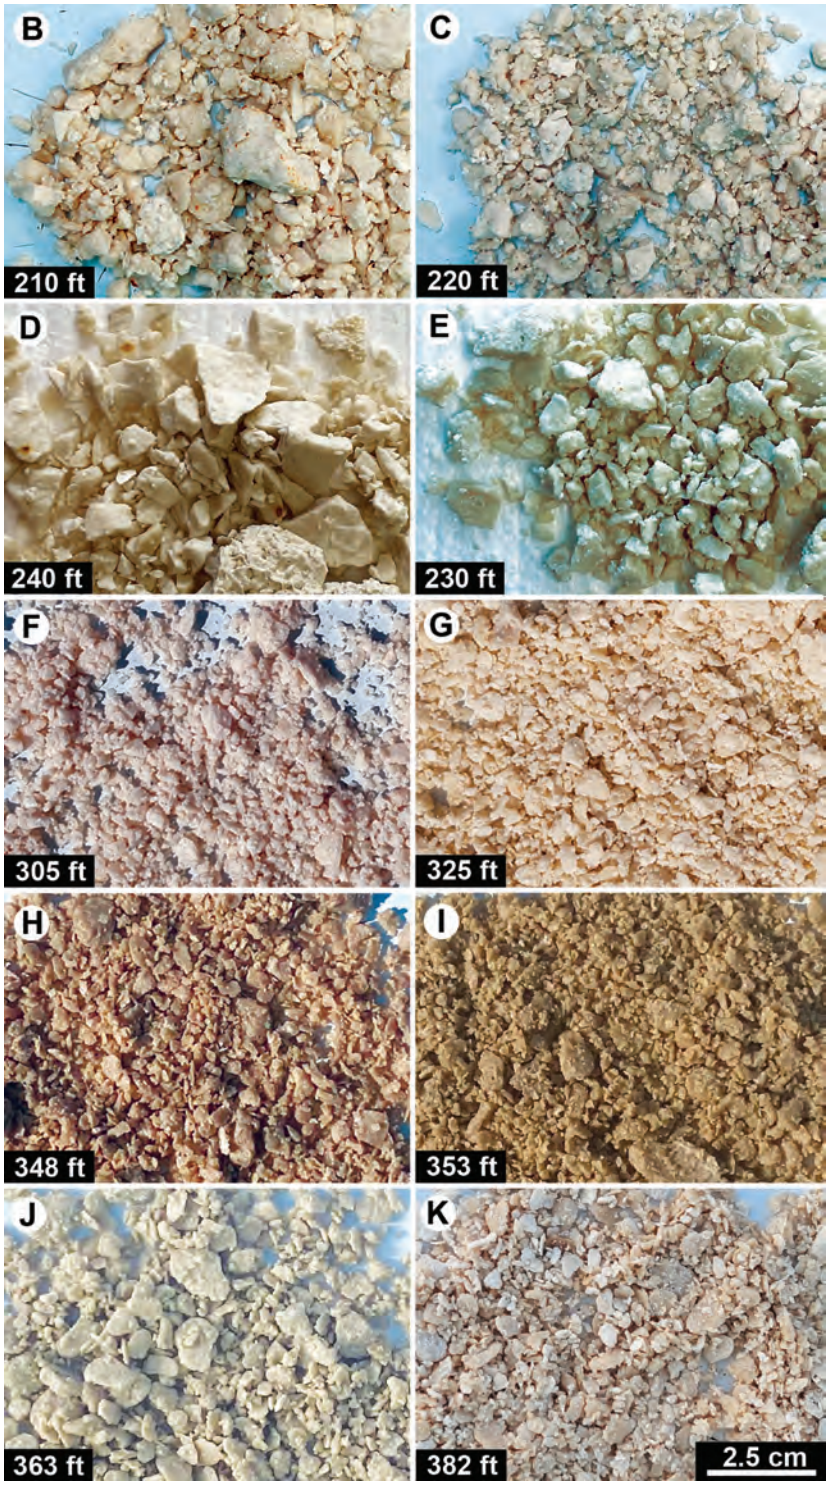

Figure 16: (A) Drill times for DUM-1 from 200 ft to base of well and locations of cores 1 to 4), insets show a segment of each core for comparative purposes. (B-K) Photographs of cuttings at various depths between 210 ft and 382 ft. Boundary between the Cayman Formation and Brac Formation lies somewhere between core 1 and core 2.

Note: *minor differences in colours in panels B to K probably reflect differences in lighting rather than the true colours of the rock fragments.*

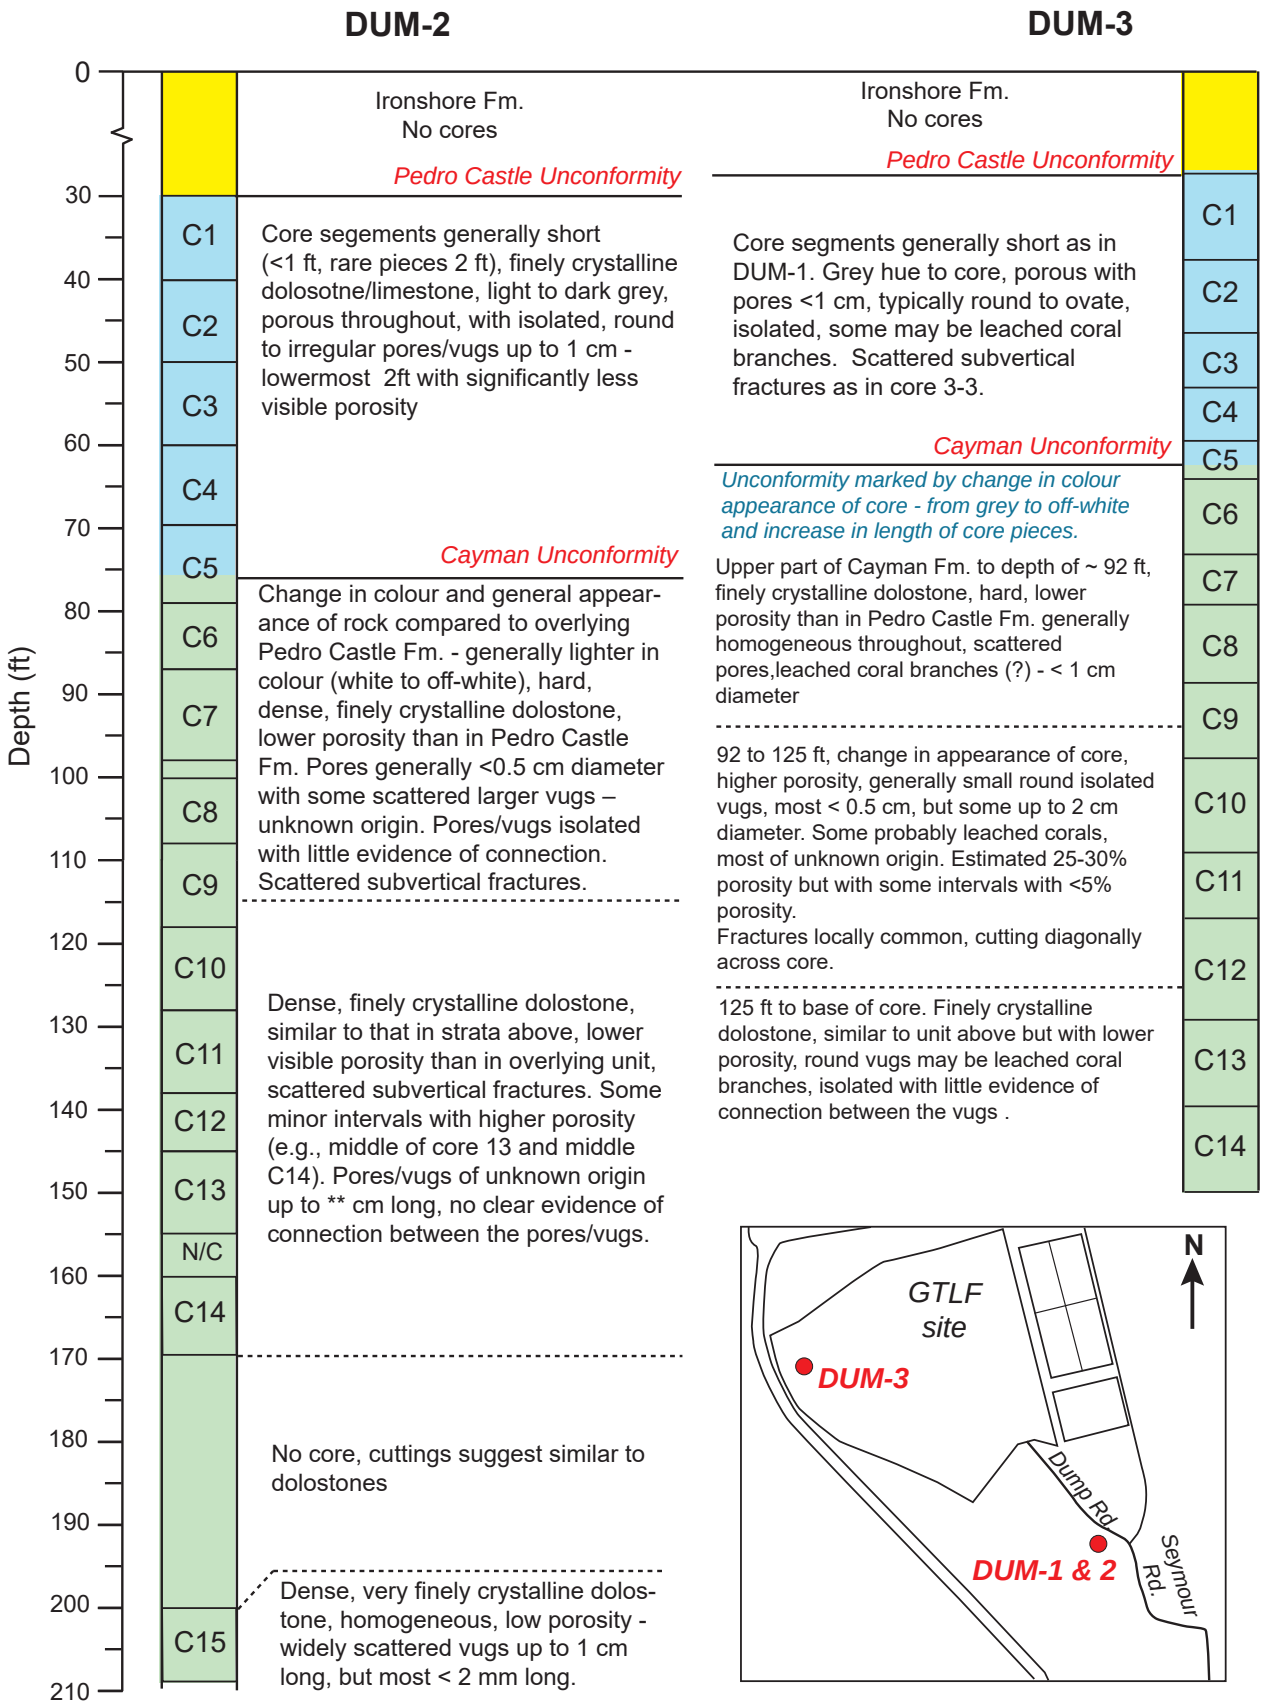

Figure 17: Correlation between wells DUM-2 and DUM-3 with summary descriptions of the cores from both wells.

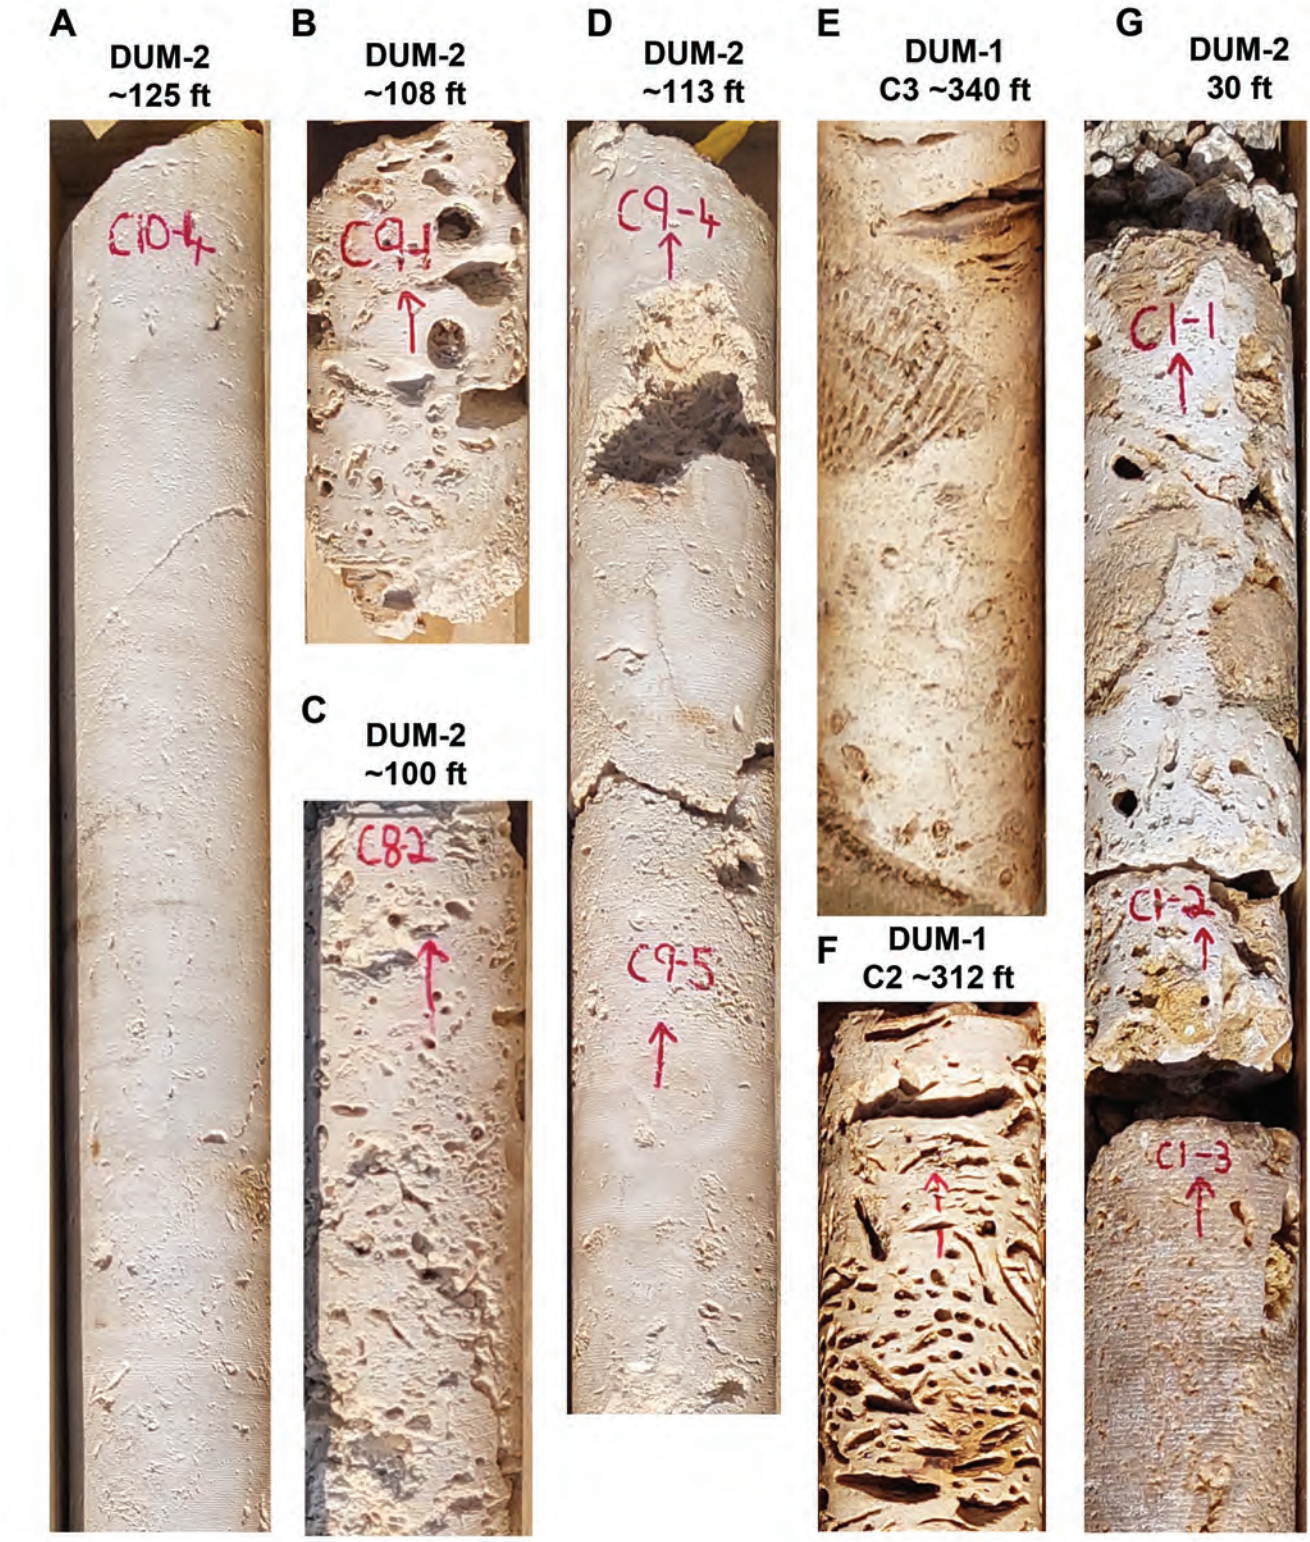

Figure 18. Examples of different styles of porosity in cores from wells DUM-1, DUM-2, and DUM-3. Locations are specified as well number, core number (e.g. C2) and depth (below drill table that is ~ 3 ft above ground level). (A) Dolostone with low porosity, pinpoint pores only. (B) Dolostone with vuggy porosity of unknown origin. (C) High porosity with pores and small vugs of unknown origin. (D) Dolostone with low porosity and leached coral (top). (E, F) examples of high fossil-mouldic porosity created by leaching of corals. (G) Upper part of Pedro Castle Formation with vugs of various sizes, some of larger vugs subsequently filled by cavity-filling sediment. All cores are 4 in (~10 cm) diameter.

DUM-2, and DUM-3, as well as many surface and subsurface samples from across Grand Cayman and Cayman Brac, shows that the following styles of porosity are present in these formations.

- ***Intercrystalline and pinpoint porosity*** (Fig. 18A). The morphologies of the intercrystalline (< 10 μm long) and pinpoint pores (> 10 μm but < 1 mm long) are controlled largely by the packing of the dolomite crystals that form the groundmass. In many cases, low permeabilities are associated with this style of porosity because there is little connection between the pores.
- ***Vuggy porosity***. This type of porosity, which developed through the late-diagenetic dissolution of the bedrock, has no obvious relationship to any fabric or structural element in the original sediment (Fig. 18B, C). Such cavities, which are generally isolated can be of any size and shape.
- ***Fossil mouldic porosity*** (Fig. 18D, E, F). This type of porosity developed when the aragonitic skeletons of organisms (e.g., corals, bivalves, gastropods) were dissolved before or during dolomitization. The size and shape of these fossil-moldic cavities, reflects the morphology of the original skeletons from which they developed (Fig. 18D, E, F). Small bivalves may lead to pores that are less than 1 cm long whereas dome-shaped cavities up to 3 m high result from dissolution of large coral heads. The distribution of this type of porosity is facies dependent because it reflects the distribution of the animals in their original depositional environment.
- ***Caves and large cavities.*** Caves and large cavities are common features in the Cayman Formation and Brac Formation on Grand Cayman and Cayman Brac. Rare caves have also been found in the Pedro Castle Formation on Cayman Brac. For example, the lower part of the wall in Pedro Castle quarry, (Fig. 6) includes a system of caves in the Cayman Formation, ~15 ft below the Cayman Unconformity, some of which are partly filled with cave precipitates (e.g., flowstone) and sediments. Crystal Caves, found on the north-central coast of Grand Cayman are a spectacular example of an extensive cave system that has developed in the Cayman Formation. Such caves, which are highly variable in size and morphology, are commonly developed just below the unconformities that separate the formations from each other. There is no recognizable pattern to their distribution or morphological development. On Cayman Brac, caves of all sizes are common in the upper part of the Brac Formation and throughout the Cayman Formation. For wells DUM-1, DUM-2, and DUM-3, caves/cavities were recorded by “bit drops” that occurred during drilling (Table 1). Given that these caves/cavities were identified solely by “bit drops” their lateral extent and overall morphology are unknown. Unfortunately, no further information was available from the down-hole video because the water was very cloudy and lateral visibility was very low.
- ***Fractures*** (Figs. 18, 19). Recognition of natural fractures in core can be difficult because the cores commonly break during drilling and/or extraction from the core barrel. Although the breaks between successive pieces of core may be along natural fractures (Fig. 19A), it is usually difficult to determine if that is the case. Assessment of the core from wells DUM-1, DUM-2, and DUM-3, however, indicates that some fractures are present (Fig. 19B). Downhole videos of well DUM-1, which reached a depth of 406 ft, showed that fractures are common between 350 and 406 ft (Fig. 20). These are treated as natural fractures because it is readily apparent that they penetrate into the wall of the borehole. Such fractures were rarely evident in the strata above 350 ft.

Table 1: Distribution of caves and cavities, as recognized by "bit drops" in well DUM-1, DUM-2, and DUM-3.

Well	Depth top (ft)	Depth bottom (ft)	Height (ft)
DUM-1	105	113	8
DUM-1	328.5	329.5	1
DUM-2	40	41	1
DUM-2	98	99	1
DUM-2	108	109	Hole collapse
DUM-2	113	114	6 in cavity
DUM-3	52	53.5	1.5
DUM-3	83	84	0.5
DUM-3	137	138	0.5
DUM-3	145	146	1

There are no recognizable patterns to the distribution of these different types of porosity. The fossil-mouldic porosity is facies controlled given that its distribution is a reflection of the distribution of the different animals (e.g., corals, bivalves) in the original depositional environments. In contrast the vuggy porosity has a random distribution because it formed as a result of diagenetic processes that were mediated by groundwater passing through and dissolving parts of the bedrock.

The situation is further complicated by the fact that some pores, vugs, and/or cavities were later occluded by dolomite and calcite cements and/or internal sediment. In the upper part of core 1 from DUM-2, for example, dissolution vugs were later filled by internal sediments that are readily evident because their colours are different from that of the original bedrock (Fig. 18G). These processes led to a decrease in the porosity of the rocks and may, in some cases, have caused a decrease in the permeability of the limestones and dolostones.

POROSITY IN DUM-1 and DUM-2

Porosity in wells DUM-1 and DUM-2, which penetrated the Pedro Castle Formation, Cayman Formation, and Brac Formation, is assessed from the core from DUM-2 (30 to 210 ft - Appendix B) and the downhole video for DUM-1 from 165 ft to 405 ft (Figs. 21, 22).

Core from DUM-2, which includes the Pedro Castle Formation and the upper part of the Cayman Formation, has variable porosity characteristics. Core from the Pedro Castle Formation (C1 to approximately the base of core 5; 30 to ~76 ft) is formed of finely crystalline dolostones that are generally characterized by high visible pinpoint and vuggy porosity. Porosity is variable throughout this part of the succession. Vugs up to 10 cm but typically < 5 cm long are common throughout. There is no obvious origin to the irregular-shaped vugs.

The Cayman Formation, from ~ 76 ft to the base of the core, is formed of dolostones with variable porosity. Between 76 and 100 ft, it is formed of finely crystalline dolostones with pinpoint and vuggy

Figure 19. Examples of natural fractures in cores from wells DUM-1 and DUM-2 at depths of ~376 ft and ~115 ft, respectively. Core is 4 in (~10 cm) in diameter.

porosity, with most vugs <1 cm long (e.g., C5-2). Below 100 ft, the porosity is more variable. Below 108 ft there are scattered vugs and some fractures (e.g., C9-6) whereas other parts have little visible porosity (e.g., C10-4). Below 115 ft there is a notable decrease in visible porosity with only scattered vugs and pinpoint porosity being evident. Some intervals (typically < 1 ft thick) are characterized by fossil-mouldic porosity, possibly after branching corals (base of C13-3). Low porosity is evident to the base of core 15 at a depth of 205 ft.

The downhole video from DUM-1 shows relatively consistent patterns of porosity from 165 to 405 ft (Figs. 21, 22). Panoramic views of the walls of the borehole show a relatively consistent pattern of pinpoint porosity with small vugs at various depths. Some of the larger vugs probably formed through the dissolution of the aragonitic skeletons of branching corals (e.g, Fig. 21D, J, K, 22D-F). Below ~330 ft there is a notable change in porosity style with thin, elongate pores (long axes parallel to bedding) being dominant (Fig. 22G-R). The origin of these pores is unknown. From 350 ft to the base of the well at 404 ft, there are numerous well-developed fractures (Fig. 20) that contribute to the overall porosity and also provide avenues for water flow.

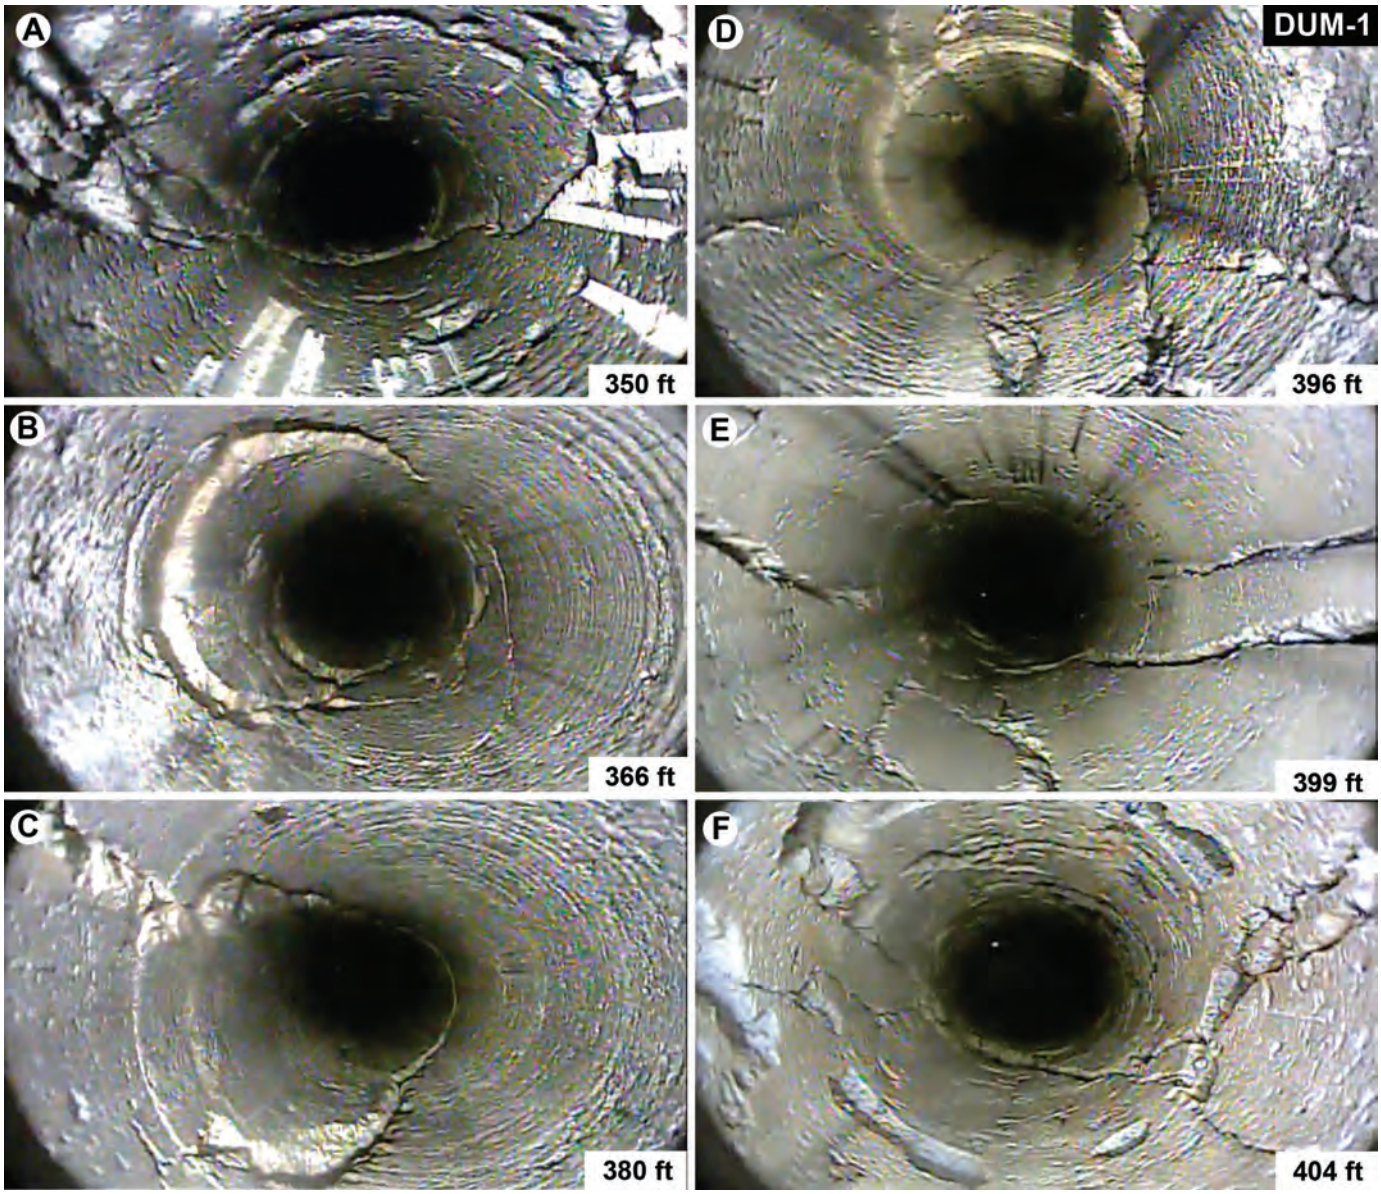

Figure 20. Examples of natural fractures evident in downhole video from DUM-1/2. Specified depths are below ground level.

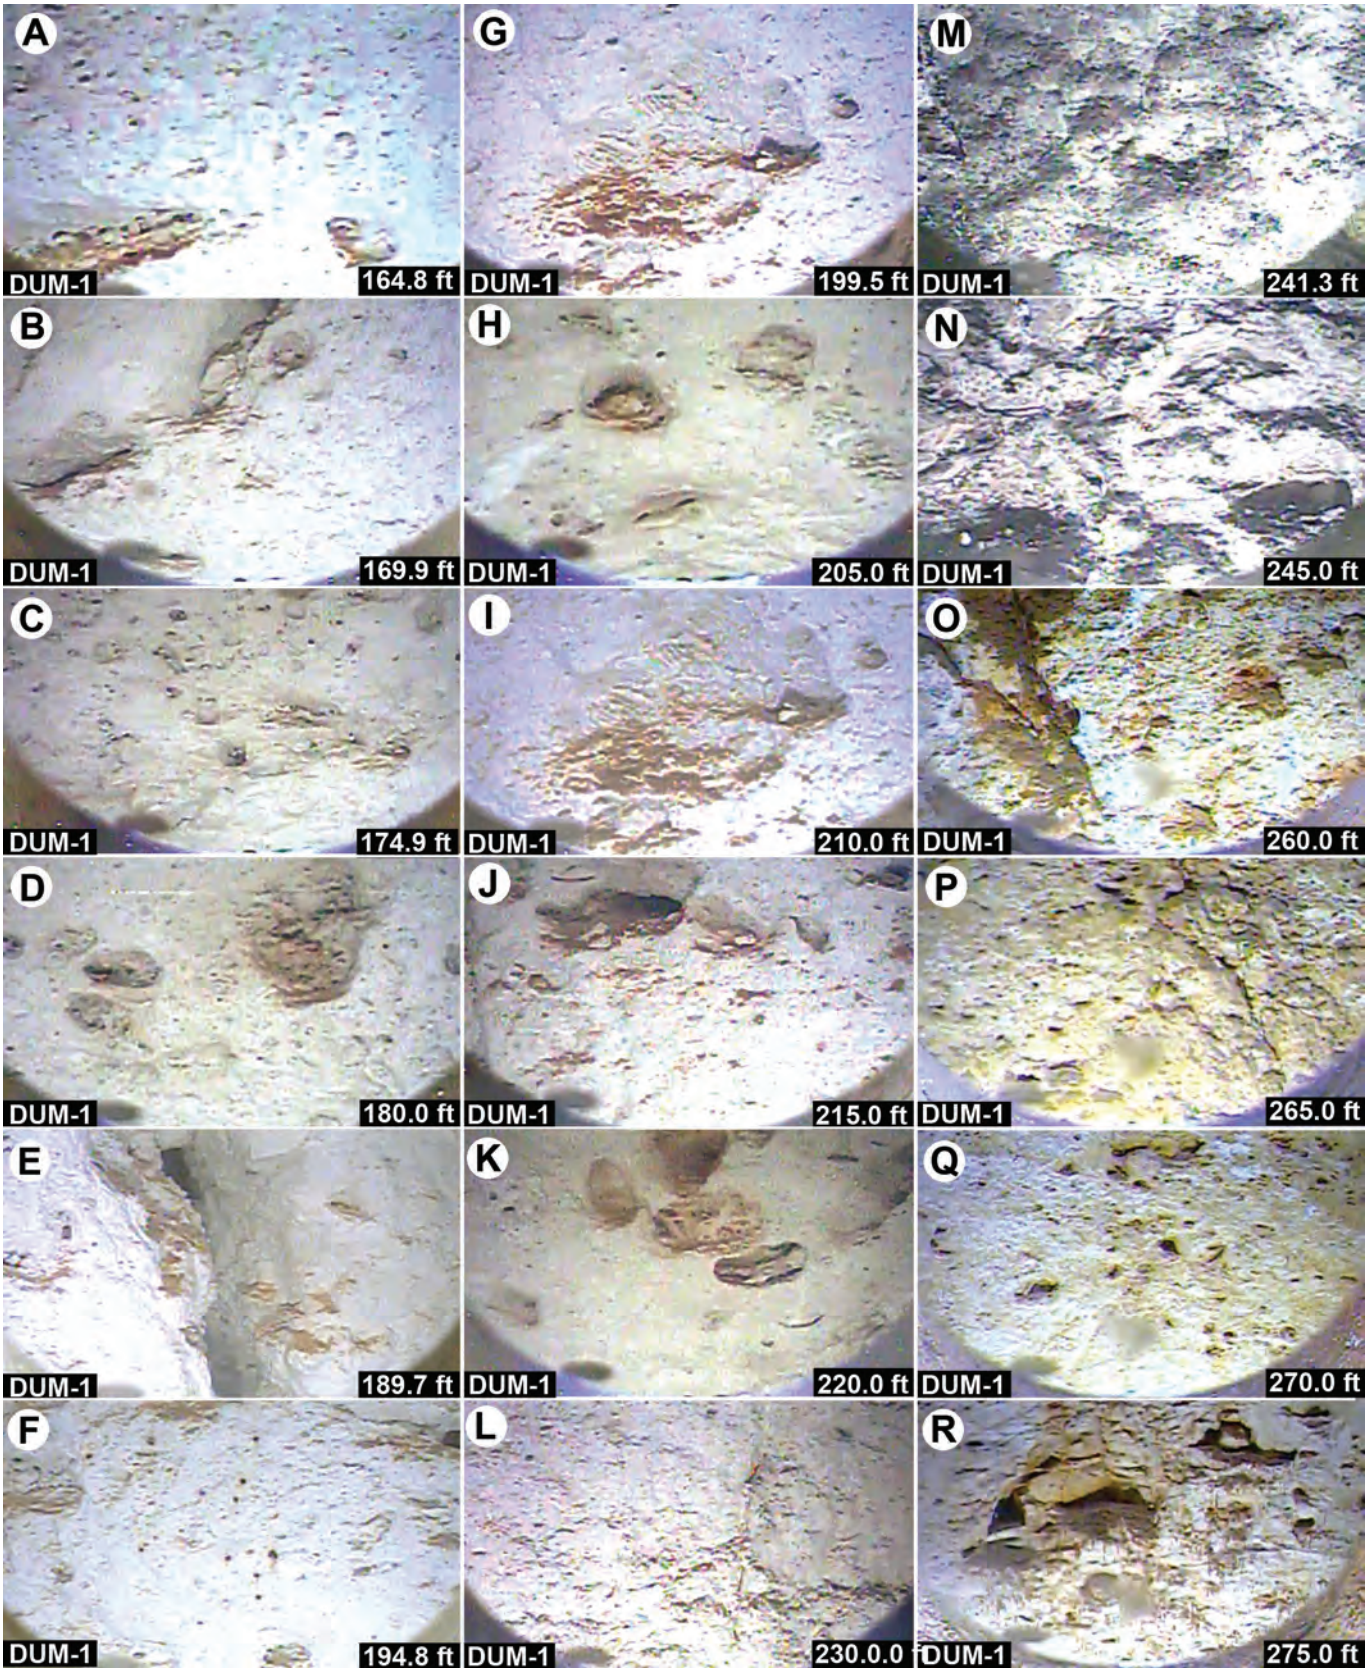

Figure 21. Views of wall of borehole DUM-1 from 164.8 to 275 ft (from downhole video) through Cayman Formation, showing generally homogeneous finely crystalline dolostones with low porosity and scattered, isolated fossil-mouldic porosity (after corals - e.g., panels D and K) and fracture in panel E. Although no scale bar is available for the downhole video, each field of view shown above is estimated to be about 2 in (~ 5 cm) wide. Specified depths are below ground level.

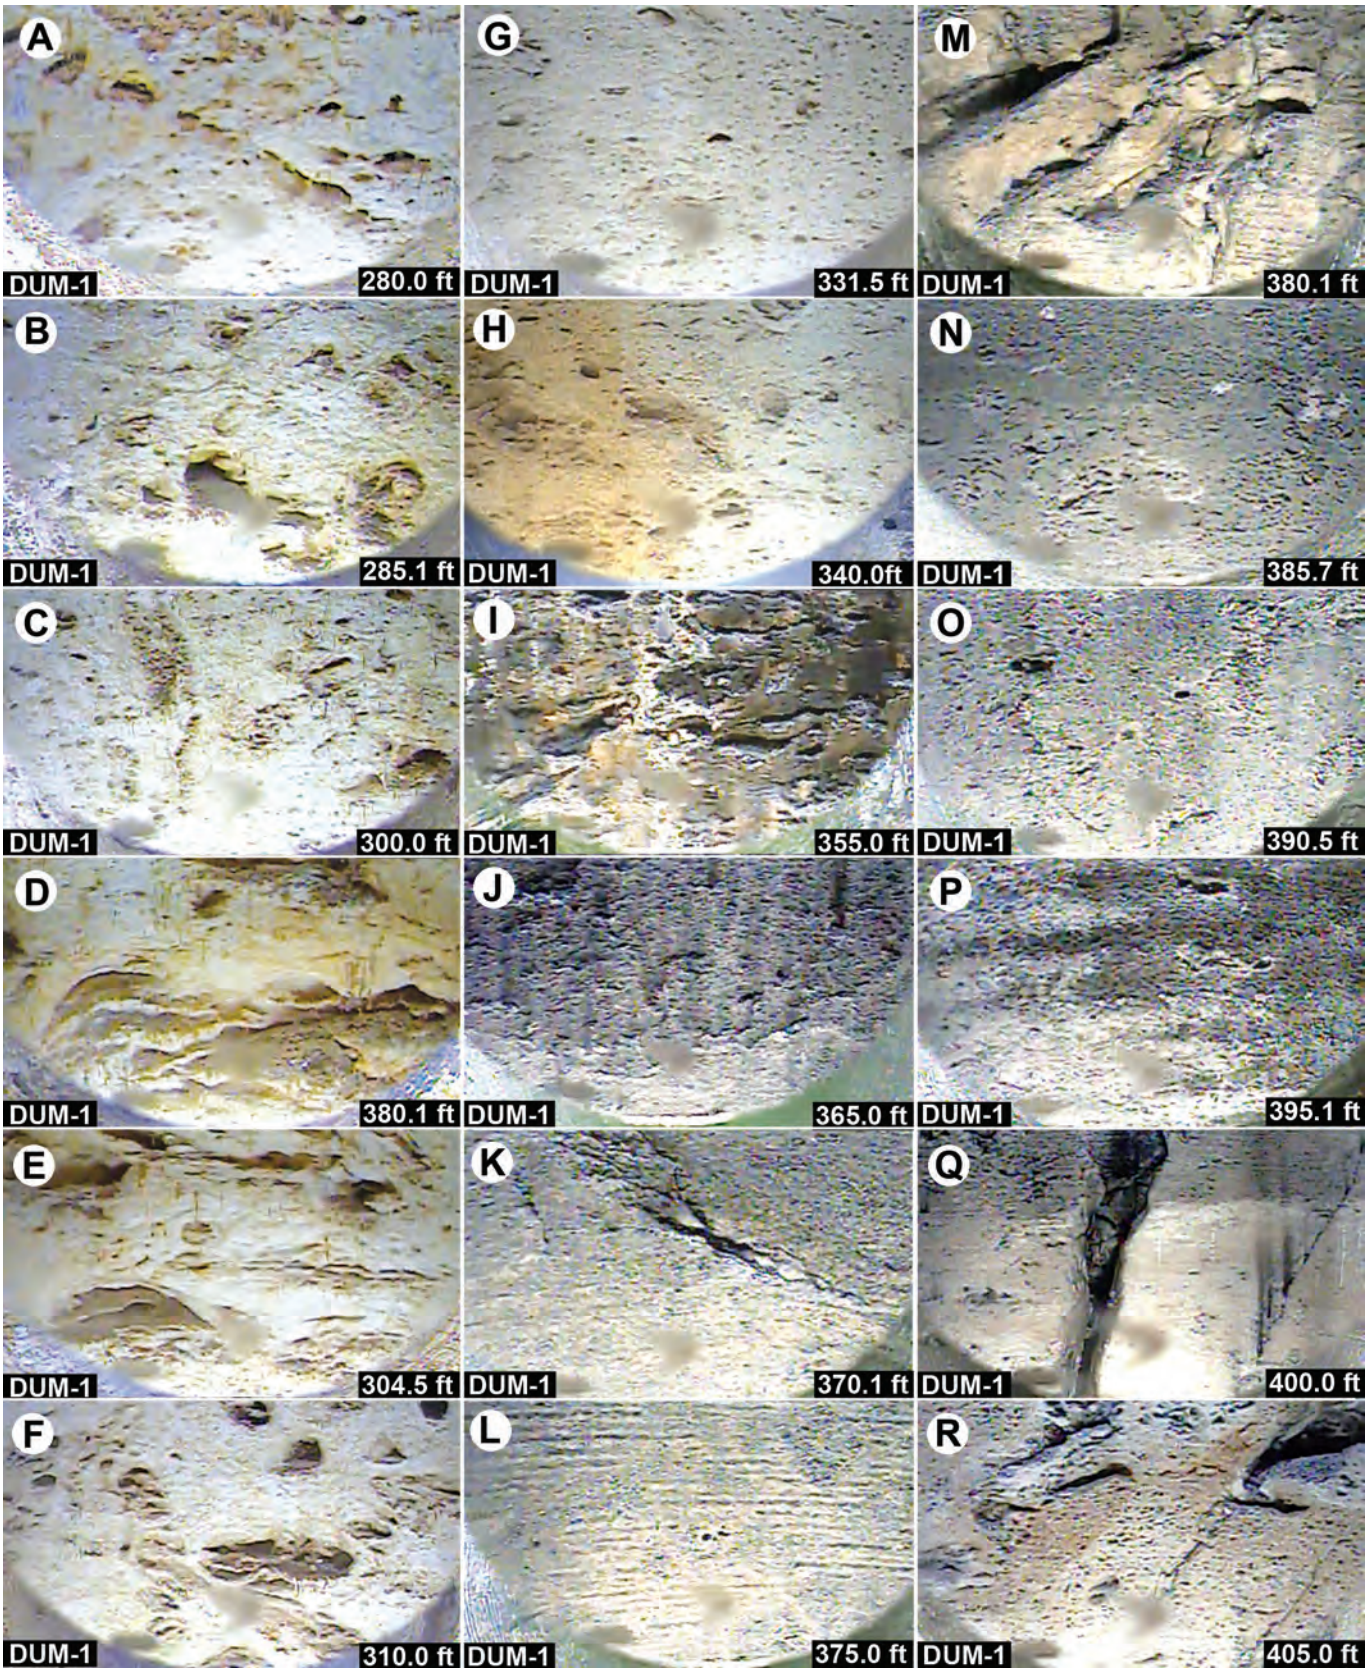

Figure 22. Views of wall of borehole DUM-1 from 280 to 405 ft (from downhole video) through the Cayman Formation and Brac Formation (boundary at ~250 ft), showing variable textures in finely crystalline dolostones with variable porosity that is a mixture of matrix porosity and fossil-mouldic porosity (C to F) and fracture in panels K, M and Q. Although no scale bar is available for the downhole video, each field of view shown above is estimated to be about 2 in (~ 5 cm) wide. Specified depths are below ground level.

TESTED POROSITY/PERMEABILITY

Twenty-eight whole core porosity and permeability analyses were obtained for various core segments from wells DUM-1 (4 samples), DUM-2 (16 samples) and DUM-3 (8 samples). The analyses, performed by Core Laboratories (Houston), included 6 samples from the Pedro Castle Formation, 18 samples from the Cayman Formation, and 4 samples from the Brac Formation (Table 2, Figs. 23-26). For each sample, the permeability (Kmax, K90, Kvert), porosity, and grain densities were determined.

Table 2. Tested porosity, permeability (Kmax, K90, Kvert, porosity, and grain density for selected core samples from wells DUM-1, DUM-2, and DUM-3.

Well	Core Segment	Depth (ft)	Sample Depth (ft)	Kmax (mD)	K90 (mD)	KVert (mD)	Porosity (%)	Grain Density

It is important to remember that the tested porosity and permeability values do not include any fracture porosity/permeability (Fig. 20) or large cavities that may be present in the system.

Examination of the fabrics evident in the core segments from which the measured porosity and permeability data were determined (Figs. 23-26) clearly demonstrates the difficulty of trying to estimate these parameters on the basis of visual inspection of the cores. Core 1 (C1) and core 2 (C2) from DUM-1 (Figs. 23A and 23B, respectively), for example, have tested porosities of 21.3% and 13.4%, respectively. Visually comparisons, however, might suggest that the opposite was true given that obvious, large vugs evident in core 2 (Fig. 23B). As with many other cores from DUM-1, DUM-2, and DUM-3, much of the porosity is intercrystalline (i.e. pinpoint) and hence difficult to detect in hand samples. This issue is also clearly illustrated in cores from DUM-2 that are formed largely of finely crystalline dolostone and have tested porosities ranging from 11.4 to 39.7% (Figs. 24, 25). The same is also true for the tested cores from DUM-3 (Fig. 26). Comparison of the measured permeabilities and porosities obtained from the samples from the Pedro Castle Formation, Cayman Formation, and Brac Formation shows that there in considerable variation in all parameters with no discernible patterns to those variations (Tables 2, 3). This variation is also clearly evident in the down-hole plots of each of these parameters (Fig. 27).

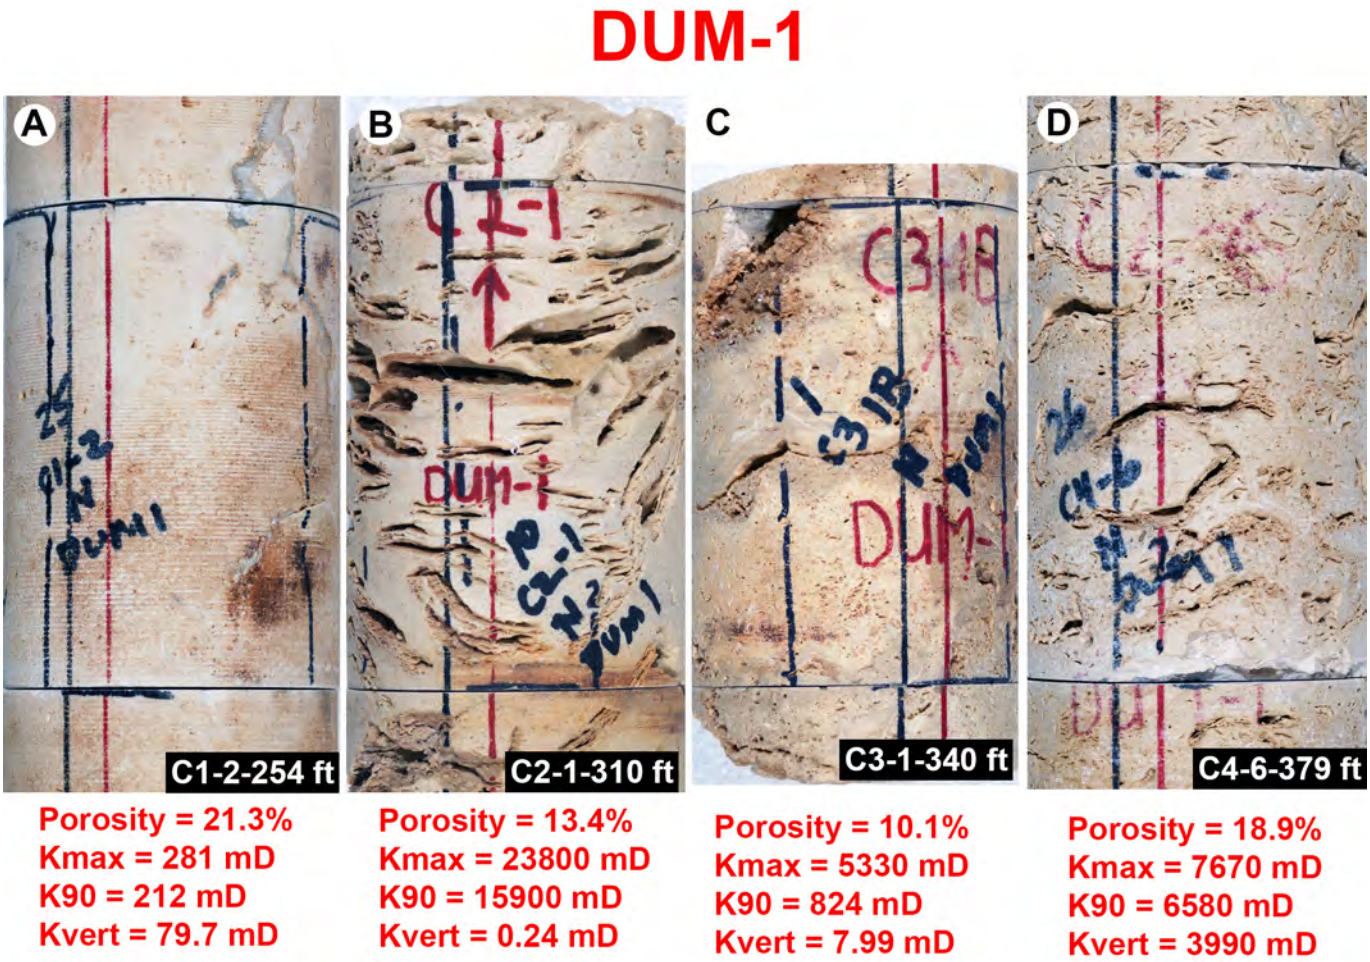

Figure 23. Images of core samples from DUM-1 used for determining tested porosity and permeability. Horizontal cuts across core define limits of core segment used for testing. Positions of core, indicated in bottom right corner of each image gives the core number (e.g., C1-2 and approximate depth of core segment) – see Appendix for images of the entire cores. Markings on core relate to the testing methodology.

Porosity in the samples from the constituent formations ranges from 10 to 40%, with seemingly random variance throughout the succession (Fig. 27). Similarly, Kmax ranges from 0.1 to 23800 mD without any identifiable stratigraphic trends being evident (Fig. 27). Comparison of the porosity and Kmax (Fig. 28) shows that there is no obvious correlation between these two parameters and further emphasizes the degree of variance among these data. The range of permeability (Kmax, K90, Kvert) and porosity values are generally the same for the Pedro Castle Formation, Cayman Formation, and Brac Formation (Table 3).

Collectively, these data indicate that the porosities, as determined from these 28 samples, generally vary from 10 to 40% throughout the succession (Fig. 28). In contrast, the permeability, as measured by Kmax, tends to be less than 5000 mD in most samples with only ten having higher Kmax values (Tables 2, 3, Fig. 28). This is true for all the samples, irrespective of the formation from which they came. For wells DUM-1, DUM-2, and DUM-3, there is no obvious pattern or explanation for the distribution of the layers with high permeabilities.

CORRELATION WITH STRATA IN SURROUNDING AREA

The stratigraphic succession in wells DUM-1 and DUM-2 amd DUM-3 is essentially the same as that seen in the wells that have been drilled elsewhere on the western part of Grand Cayman. There are, however, variations in the thicknesses of the formations and differences in the depths of the formation boundaries. One of the key issues with respect to these wells is the presence/absence of the "cap rock" at the top of the Cayman Formation, which was first identified in well LV#2 based on downhole drilling rates and tested porosity/permeability values (Fig. 5). In the absence of tested porosity/permeability values, identification of the cap rock based solely on drilling rates is complicated by the fact that four different types of drill rigs have been used to drill the wells in the area around the GTLF site and sewerage works. The locations of the cap rock in wells DUM-1 and DUM-2 and DUM-3 are difficult to delineate because there is little downhole variance in the drilling rates (Figs. 10, 11). The wells drilled to the north of the old sewerage work site were drilled using a wire-line system without drilling times being recorded. Accordingly, the identification of the cap rock in the DUM wells and nearby wells must be treated with some caution.

Well SHT#4, drilled 650 ft to the northeast of DUM-1 and DUM-2 is important because it is the deepest well drilled in the area (480 ft), it was fully sampled with the collection of cuttings and numerous cores. Tested porosity and permeability values were obtained from many of the cores (Fig. 8). In that well, the Pedro Castle Unconformity was at a depth of 30 ft, the Cayman Unconformity was at 50 ft, and the Brac Unconformity was tentatively placed at ~260 ft. Based on drilling rates and low tested porosity/permeability values in the upper part of the Cayman Formation, the lower boundary of the "cap rock" was placed at about 105 ft, but it should be noted that it was not clearly defined. In SHT#4, all tested porosities were below 15% for the Pedro Castle Formation and Cayman Formation to a depth of 210 ft and for most of the Brac Formation (Fig. 29). High porosities (>15%) and permeabilities were only found in the basal part of the Cayman Formation between 210 and 260 ft (Figs. 29, 30).

Comparison of the DUM wells with two other wells on the western part of Grand Cayman further illustrates the highly variable nature of the "cap rock", and the porosity and permeability of the constituent formations. Well GET#1 was drilled 1.7 km to the SSW of the DUM wells, whereas well GTH#1 was drilled 1.7 km to the NNW of the DUM wells (Fig. 1). In well GET#1, the Ironshore Formation was ~10 ft thick, whereas the base of the Cayman Unconformity is at ~80 ft and the base of the Brac Unconformity is at ~240 ft (Fig. 29). For this well, 22 samples from 8 cores (up to 3 samples were taken from individual cores that were up to 10 ft long) showed that the Cayman Formation and Brac Formation were characterized by low porosity (<20% with most <10%) and permeability values (Figs. 29, 30). High porosity and high permeabilty values were only recorded from one core (3 samples) that came from the Pedro Castle Formation (Fig. 29). The "cap rock" in the Cayman Formation was not identified in this well, partly because no drilling records were kept for that well.

For well GTH#1, 1.7 km NNW of the DUM wells, the pattern of porosity and permeability is different from that in GET#1 (Figs. 29, 30). In that well, the Ironshore Formation is ~10 ft thick, the

Cayman Unconformity is at ~38 ft, and the Brac Unconformity is at ~250 ft (Figs. 29, 30). Porosity and permeability values were determined for 14 samples from 9 cores from the Cayman Formation and Brac Formation (Figs. 29, 30). All of the samples from the Cayman Formation (6 samples) and Brac Formation (8 samples) had porosities between 10 and 30% except for one sample from the Cayman Formation and one sample from the Brac Formation that had porosities of 5 to 10% (Fig. 29). With the exception of one sample from the lower part of the Cayman Formation and two samples from the basal part of the well (Brac Formation) permeabilities for all samples were high. The "cap rock" in the Cayman Formation was not identified in this well.

All of the available evidence from the wells at the ReGen site and nearby areas indicate that the general pattern in the Brac Formation, Cayman Formation, and Pedro Castle Formation is of a sequence with generally low porosity and permeability values, but with intermittent units that have high porosity and high permeabilities (Figs. 29, 30). Some caution must be added to this conclusion because of the following considerations:

- The overall patterns of porosity and permeability are based on few samples relative to the depth of each well.
- The core pieces used for determining porosity and permeability are selected so that they do not have any fractures or cavities that cut through the entire diameter of the core. Downhole videos show that fractures are common in some parts of the succession in the ReGen site (Fig. 20). Such fractures will play a major role in the lateral movement of groundwater.
- Caves and large cavities, which are present at various depths, are not captured in tested porosity and permeability values.

In the simplest sense, the succession is characterized by strata with low porosities and low permeabilities but with some strata having high porosities and high permeabilities (Figs. 23, 29, 30). The situation is further complicated by the fact that the pores/vugs in many parts of the succession are isolated with little or no connection between them. There is, however, no clearly identifiable pattern to the distribution of the layers that have both high porosity and high permeability.

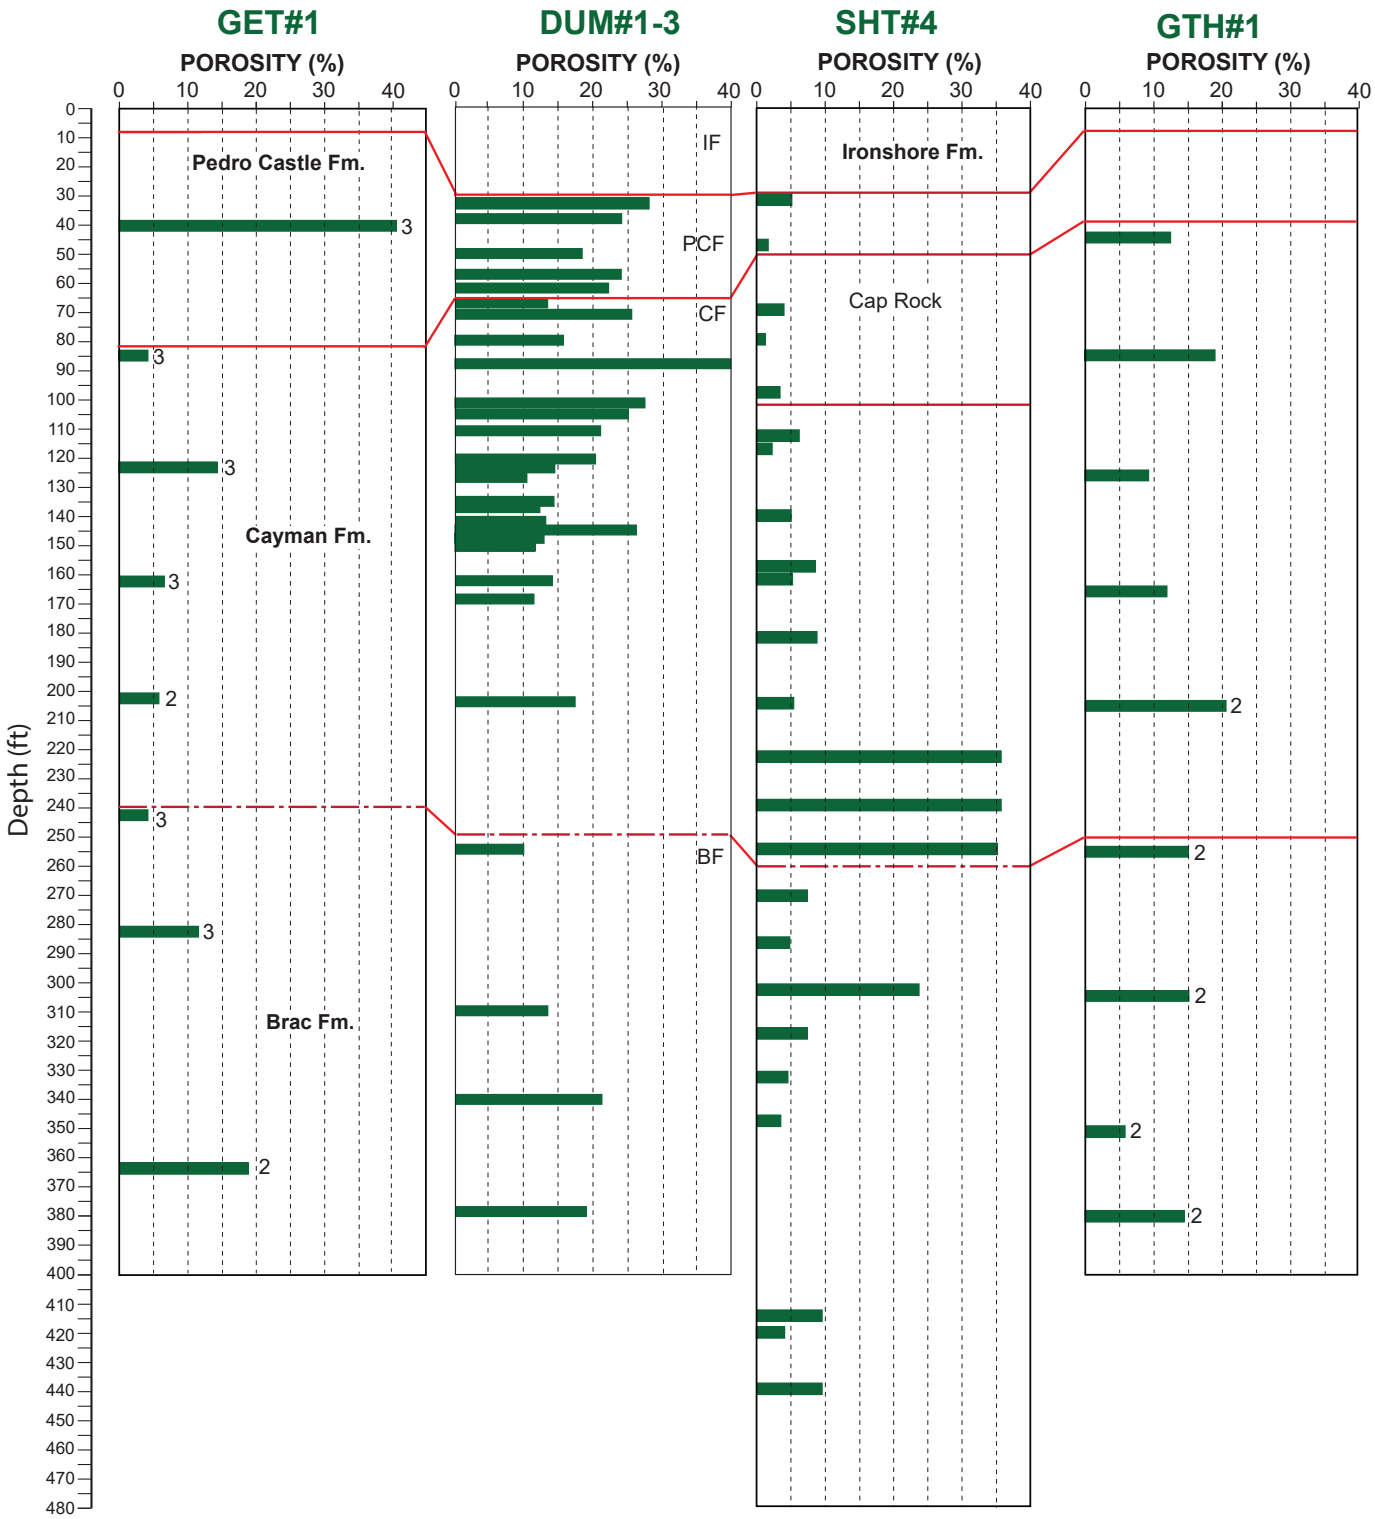

Figure 29. Comparison of porosity values for strata in wells GET#1, DUM1-3 (combined for wells DUM-1, DUM-2, and DUM-3), SHT#4, and GTH#1 (see Fig. 17 for location of wells). See Table 2 for raw data. See Figure 1 for location of wells GET#1 and Fig. 9 for location of well SHT#4. Number on right side of porosity bar indicates number of porosity values obtained from the 10 ft core at that depth - porosity value is average of those samples.

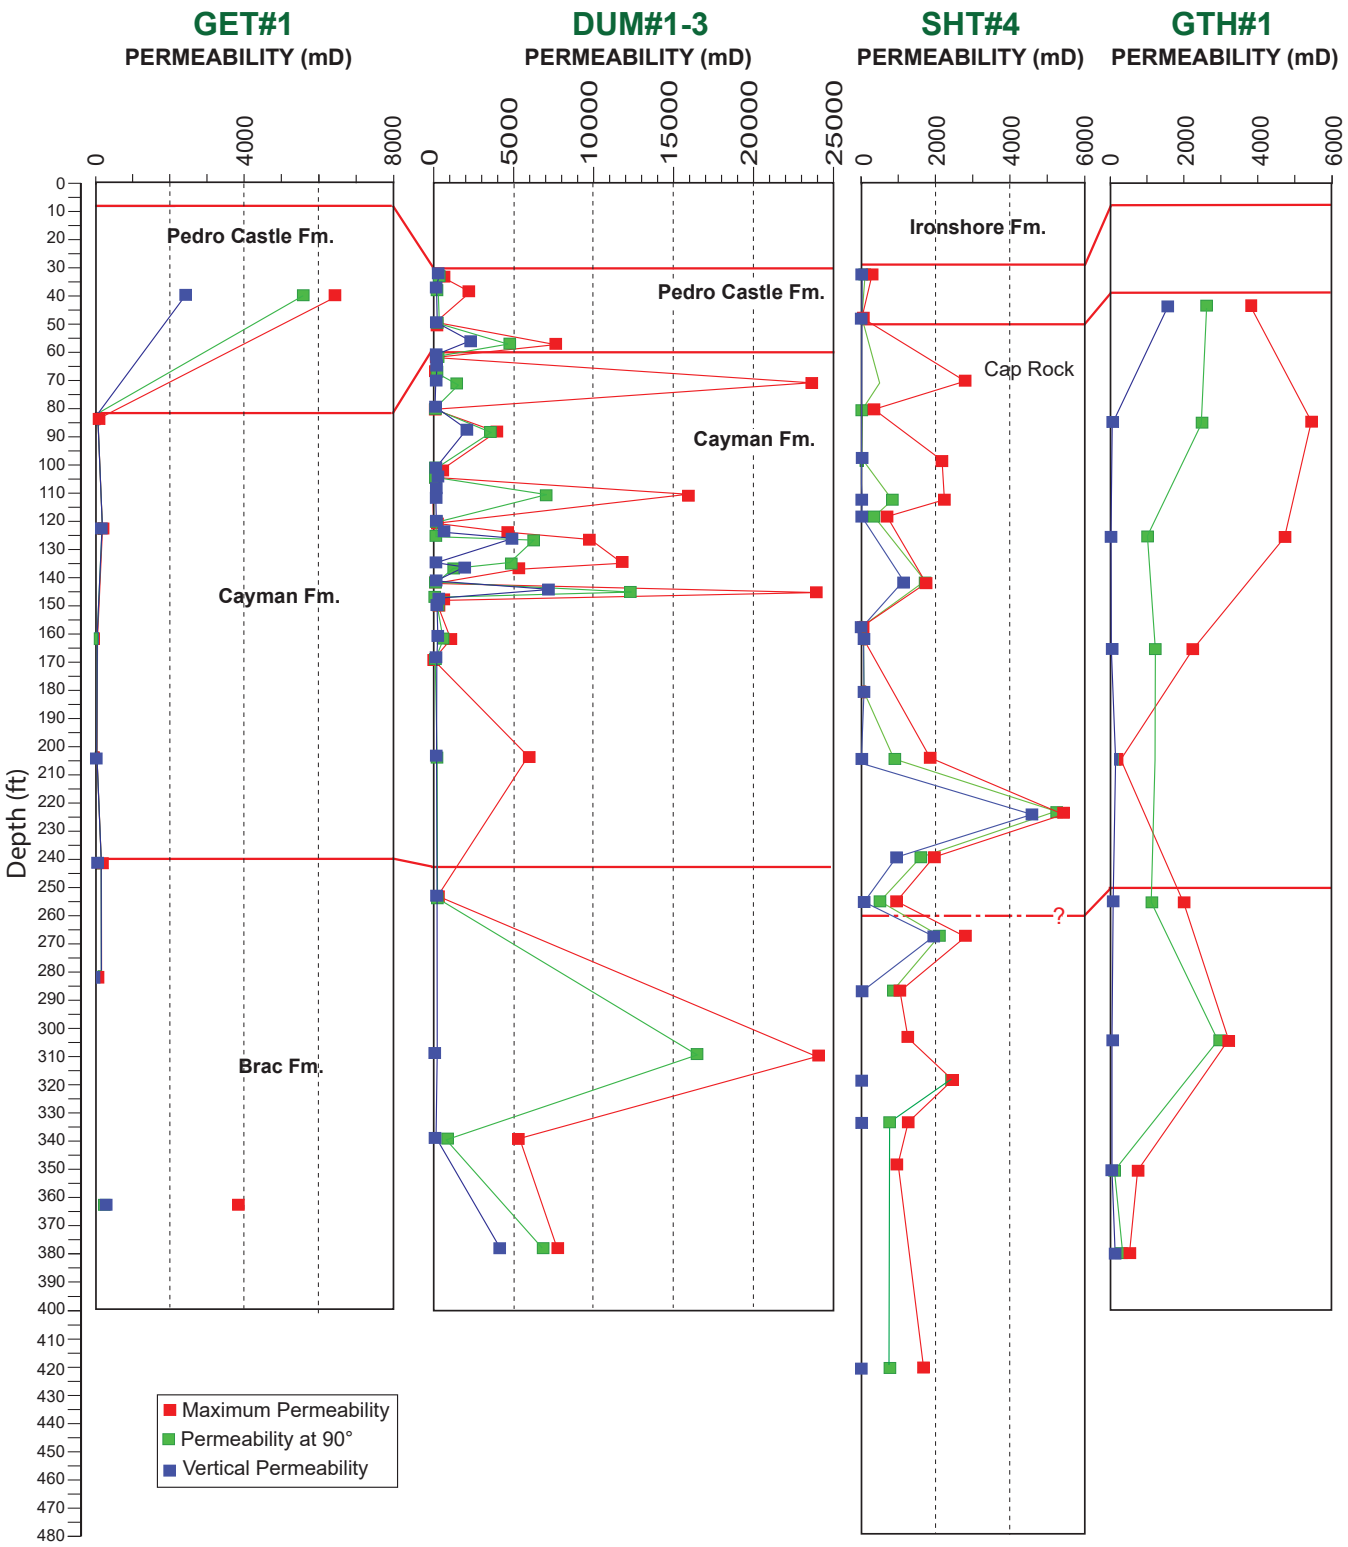

Figure 30. Comparison of permeability (Kmax, K90, and Kvert) values for strata in wells GET#1, DUM1-3 (combined for wells DUM-1, DUM-2, and DUM-3), SHT#4, and GTH#1. See Figure 1 for location of wells GET#1 and GTH#1. See Fig. 9 for location of well SHT#4.

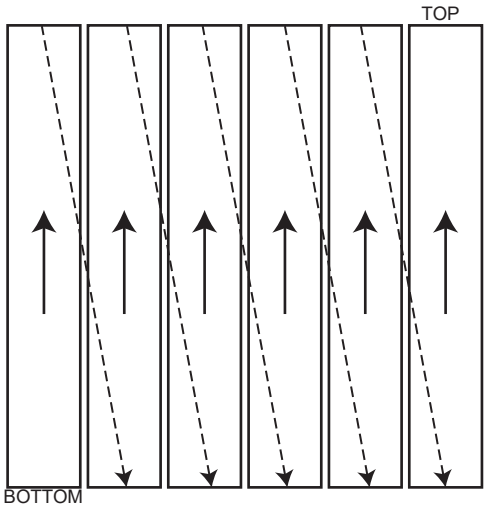
CATALOGUE OF CORES FROM WELLS DRILLED AT REGEN SITE



This Appendix provides a systematic documentation of the basic information obtained from wells DUM-1, DUM-2, and DUM-3 that were drilled at the ReGen site.

The photographs of the core are intended to give an overall view of the cores and provide a visual impression of the general lithologies, porosity, and permeability pathways. In viewing these cores the following points should be noted.

- All photographs were taken by APEC Engineering Ltd. while the core was still in the field. The variable light conditions led to variations in some false colors, shadows, and some highlights.
- The core was not cleaned prior to being photographed. Thus, the surface colours evident in the core photographs cannot be treated as being fully indicative of the true rock colour. Some of the discolouration, for example, is probably a surface stain that may have been inherited from the drilling and the core barrel.
- Every effort was made to maintain a consistent scale for all of the cores. Nevertheless, some variance can be expected because of the angles of the cores relative to the camera and the fact that in any single photograph of the core there will be a slight variance in the scale between the centre of the image and the edges of the image.

Order of Cores

In the following photographs of the cores, the core is consistently ordered as shown on the right.
The top of the core is always in the upper right corner and the bottom of the core is always in the lower left corner.

Appendix B Grand Cayman Proposed Integrated Waste Management System, ReGen, Geotechnical Investigation and Report. AEC, July 2023

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

1. Introduction

1.1 Purpose of this report

ReGen ('the proponent') is seeking approval for the development of an Integrated Solid Waste Management System (ISWMS) in the Cayman Islands ('the project'). Construction and operation of the Project is proposed to allow the existing George Town Landfill (GTLF) to be closed, remediated, and replaced with an integrated waste management philosophy based on the core principles of the international waste hierarchy.

The purpose of this report is to identify geotechnical and land quality issues that may affect the proposed development.

1.2 Overview of the proposed development

Each year, approximately 115,000 tons of solid waste is produced in the Cayman Islands, with the overwhelming majority of the material presently being managed by the GTLF. This landfill capacity is, however, finite and in accordance with the provisions of both the National Solid Waste Management Strategy for the Cayman Islands (2016) and the National Planning Framework (draft for public consultation) (2018), the ToR has been prepared in relation to the proposed development of a replacement ISWMS for the Cayman Islands.

The proposed ISWMS site is located to the north of central George Town towards the western coast of Grand Cayman, immediately south-west of the existing GTLF. The proposed ISWMS is a multi-facility development, including an energy recovery facility (ERF) and supporting non-ERF waste processing, treatment, and disposal facilities. Construction and operation of the ISWMS would allow the existing landfills in George Town, Cayman Brac and Little Cayman to be closed and remediated.

1.3 Study area

1.3.1 Spatial scope

The proposed ISWMS solution is described in detail in Chapter 4 - Proposed Project & Overview.

The ISWMS will be located to the north of central Georgetown towards the western coast of Grand Cayman (the "Site"). The proposed boundary and layout of the ISWMS is shown in Figure 1.

The Study Area considered within this report encompasses the entire footprint of the ISWMS and some of its environs. The ISWMS will include the following elements:

- Energy Recovery Facility (ERF)
- Non-Energy Recovery Facilities:
  - Site weighbridges
  - Green Waste Processing Facility (GWPF)
  - Construction and Demolition Waste Processing Facility (C&DWPF)
  - Bottom Ash Processing Facility (BAPF)
  - Abandoned and End of Life / Scrap Metal Processing Facility (ELV/SMPF)
  - Medical Waste Facility
  - Materials Recycling Facility
  - Household Waste Recycling Centre
  - Landfill Gas Facility (LGF)
  - Residual Waste Landfill (RWL)
- Ancillary Facilities:
  - Admin Building
  - Maintenance Building
  - CUC Substation

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

The Study Area also includes surrounding land within approximately 250 yards, which could potentially be affected by, or contribute to, the migration of ground gases, vapours or wind-blown dusts etc. According to the ToR (Wood, 2021), this includes:

– The existing GTLF, which lies immediately north and east of the Site;
– Parts of the land owned by the Water Authority Cayman to the east of the Site, which comprises four large former wastewater treatment lagoons (now used for sludge storage), current wastewater treatment plant, some buildings and four smaller basins;
– The mangrove and industrial and commercial development (including a concrete batching plant and a concrete block and paver stone manufacturer) to the south of the Site; and
– The Esterly Tibbetts Highway and the land immediately adjacent to it (including parts of the Lakeside Development[1]), which lies to the west of the Site.

For the avoidance of doubt, this land quality assessment excludes:

– Potential contamination effects to, or from, ground- or surface-waters, which are assessed separately elsewhere
– Potential effects resulting from the operation and subsequent closure of the existing landfills on each of the three islands (including the GTLF).

1.3.2 Sub-areas of the Site

In considering the potential geoenvironmental effects, within this report the ISWMS site has been considered as 4 sub-areas as shown in Figure 2:

– **Area 1**: Consists of the northern third of the main ISWMS site, which will include the Residual Waste Landfill (including the hydrated lime and bottom ash weathering areas), the Medical Waste Facility and Leachate Management Facility. It is assumed that, in general, workers will predominantly be outdoors in this area with minimal above-ground buildings and structures (in which gases and vapours may accumulate) and that appropriate PPE and working practices will limit exposure to any soil contamination;
– **Area 2**: All other ISWMS components in the south of the main ISWMS site, including the ERF and admin areas etc. It is understood that this area will include above ground buildings and structures and that workers may be indoors and have no or limited PPE;
– **Area 3**: The CUC Substation, where it is not anticipated that workers will be present except for infrequent maintenance; and
– **Area 4**: Landfill Gas Facility (LGF) will be constructed on the 'Old Landfill' but full details of the facilities construction and operation are not currently available.

1.3.3 Temporal scope

The temporal scope considered within this report covers the construction, operation and decommissioning of the ISWMS. GHD understands that the design life of the new facilities is 25 years.

[1] This development comprises 12 three-storey residential apartments with car parking and leisure/landscape areas (including a small lake)

2. Methodology

2.1 Relationship with other sections of the EIA

This Land Quality Assessment in part overlaps with matters considered in other assessments within the EIA. In particular, as highlighted within the ToR (Wood, 2021) "*The land quality baseline is also inter-related with, and uses information from, other sections of this ToR, particularly … Hydrology (including flood risk) and hydrogeology*". The hydrology and hydrogeology chapter of the EIA are now also being prepared by GHD and due regard has been given to coordinate these chapters. However, land contamination-related dust and odour issues may also be relevant to the Air quality and greenhouse gases emissions assessment.

2.2 Potential receptors

The ToR (Wood, 2021) identified the main potential land quality receptors that could be affected by the proposed development. No additional potential receptors have been identified during this assessment.

However, it should be noted that the most significant receptor for any land contamination is likely to be the water environment (ground and surface waters), which are excluded from the remit of this assessment. The potential effects on surface and ground water receptors are considered within a separate hydrology and hydrogeology assessment.

Table 1 Potential land quality receptors identified in the ToR (Table 5.22 in Wood 2021)

Receptor	Location
Site staff, construction workers and visitors (human health)	Proposed development site
ISWMS infrastructure	Proposed development site
Surrounding land users e.g. residential, commercial/industrial, schools* (human health)	Surrounding land

Notes: * Some surrounding land users may be too far away for there to be any relevant potential contaminant linkages.

2.3 Assessment methodology

The assessment methodology was based on that prescribed within the ToR (Wood, 2021).

The geotechnical and geoenvironmental assessments are generally addressed under separate sections within this Land Quality Assessment.

2.3.1 Consistent terminology

To assist the reader, consistent terminology has been adopted within this Land Quality Assessment. In particular, the word 'effect' is used to describe the consequence of environmental changes that are caused by development-related activities. The word 'impact' should not be used other than in the phrase EIA or where it appears in references).

2.3.2 Review of existing conditions

Available secondary sources of information were collected and reviewed to characterize the existing land quality conditions within the Study Area. A number of documents were identified within the ToR (Wood, 2021) but, in preparing this Land Quality Assessment, GHD identified additional relevant documents. All documents referred to have been cited within the text and fully referenced in Section 11.

It should be noted that where data (e.g., contaminant analysis results) required extraction from the electronic documents (e.g., PDF) provided, this has been done on a 'best endeavours' basis. Where necessary, scanned images

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

were converted using optical character recognition (OCR) technology. However, GHD has not cross-checked the accuracy of the original 3rd party data nor the fidelity of any OCR or transcription, whether manual or digital.

The following sources of secondary information (listed chronologically) have been considered in relation to geology and ground conditions (geotechnical matters):

– Cruise Berthing Terminal for Cayman Islands - Final EIA Terms of Reference (Mott MacDonald, 2013)
– Grand Cayman Waste Management Facility Draft Environmental Statement (Carddno ENTRIX, 2013)
– Landfill Site Environmental Review Task 1: Environmental Investigations and Risk Assessments (Amec Foster Wheeler, 2016a)
– Landfill Site Environmental Review Task 2: Environmental Investigations Interpretative Report, (Amec Foster Wheeler, 2016b)
– Grand Cayman Proposed Integrated Solid Waste Management Facility: Energy Recovery Facility -Geotechnical Investigation and Report (APEC 2021)
– Integrated Solid Waste Management System for the Cayman Islands: Environmental Impact Assessment- Terms of Reference (Wood, 2021)

The following sources of secondary information (listed chronologically) have been considered in relation to land quality, contamination and ground gases (geoenvironmental matters):

– Memorandum: Environmental tests carried out at hurricane debris sites, CIRO (2005)
– Landfill Site Environmental Review Task 1: Environmental Investigations and Risk Assessments (Amec Foster Wheeler, 2016a)
– Landfill Site Environmental Review Task 2: Environmental Investigations Interpretative Report, (Amec Foster Wheeler, 2016b)
– National Solid Waste Management Strategy for the Cayman Islands (Amec Foster Wheeler, 2016c).
– Grand Cayman Residual Waste Composition Analysis 2016 (Amec Foster Wheeler, 2016d).
– Grand Cayman Waste Management Facility Draft Environmental Statement (Carddno ENTRIX, 2013)
– Technical note: Georgetown and Cayman Brac Landfills: Review of DEH Monitoring Report, 31 January 2017 (Amec Foster Wheeler, 2017b)
– Technical note: Georgetown Landfill Site: Surface Emissions Survey September 2016 (Amec Foster Wheeler, 2017a)
– Technical note: Georgetown Landfill Site: Surface Emissions Walkover Survey, April 2018 (Wood, 2018)
– *Cayman Island's Landfill Report Summary 2020: Supplementary Information,* EHL (2020)
– *Cayman Island's Landfill Report Summary 2020: Supplementary Information,* EHL (2021)
– Integrated Solid Waste Management System for the Cayman Islands: Environmental Impact Assessment- Terms of Reference (Wood, 2021)
– Georgetown Landfill: Environmental Risk Based Assessment (GHD, 2021a)
– Georgetown Landfill: Remediation Options Report (GHD, 2021b)

2.3.3 Site visits, inspections and investigations

It was not possible for GHD to undertake bespoke site visits or surveys nor undertake any additional site investigations during the preparation of this Land Quality Assessment. Consequently, the geotechnical and geoenvironmental assessments are based on pre-existing environmental investigation and assessment reports relating to the Study Area.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

2.3.4 Geotechnical (land stability) assessment

Based on the information reviewed, the assessment of potential geotechnical effects involved:

– Describing the baseline geotechnical conditions at the Site and the variability within them;
  - Outlining the regional tectonic and seismic information;
  - Identifying factors that may affect the future baseline.
– Assessing any land instability risks to identify any significant effects;
  - Details of the method adopted to determine the significance of each effect is presented in Section 2.3.7.
– Consideration of the influence of any cumulative effects
– Presenting relevant mitigation measures for any significant effects following accepted engineering practice standards with clear confirmation that the proposed mitigative solutions are technically and environmentally sound.

2.3.5 Geoenvironmental (land contamination and ground gases) assessment

Based on the information reviewed, the assessment of potential geoenvironmental effects involved:

– Describing the development history of the Site;
– Describing baseline geoenvironmental conditions[2];
  - Identifying factors that may affect the future baseline
– Assessing any land contamination risks to identify potentially significant effects;
  - Details of the method used to assess each risk (presented in Section 2.3.5.1);
  - Details of the method adopted to assess the significance of each effect (presented in Section 2.3.7).
– Assessing any ground gas or vapour risks to identify potentially significant effects; and
  - Details of the method used to assess each risk (presented in Section 2.3.5.2);
  - Details of the method adopted to assess the significance of each effect (presented in Section 2.3.7).
– Consideration of the influence of any cumulative effects; and
– Presenting relevant mitigation measures for any significant effects following accepted engineering practice standards with clear confirmation that the proposed mitigative solutions are technically and environmentally sound.

2.3.5.1 Land contamination risk assessment

As requested in the ToR (Wood, 2021), the assessment of land contamination was conducted, where possible, in line with UK Environment Agency's online Land Contamination Risk Management (LCRM) guidance[3], which:

– Adopts the sources-pathways-receptors paradigm;
– Requires the development and incremental refinement of a Conceptual Site Model (CSM); and
– Relies heavily on BS10175 (BSI, 2017).

Very little quantitative soils quality data relevant to the Site is available. In line with LCRM, where such data is available, Generic Quantitative Risk Assessment has been undertaken using appropriate Generic Assessment Criteria (GAC).

[2] Very limited quantitative data related to the levels of contamination with the soils and emissions of ground gases and vapours within the footprint of the ISWMS were identified. The baseline presented is therefore based mainly on a qualitative assessment of the available information.

[3] https://www.gov.uk/government/publications/land-contamination-risk-management-lcrm . Accessed 7th Sept 2021

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

The ToR (Wood, 2021) states that the Florida Administrative Code (FAC) (State of Florida, 2005), Contaminant Cleanup Target Levels (CCTL) are the GAC for potential human health risks relevant to the Cayman Islands *"considering geography, climate and given that the FAC levels also consider marine surface water criteria, which is an important factor for the islands*". Given the nature of the waste treatment and landfill facilities of the ISWMS, the CCTL for 'Commercial/Industrial' landuses ($CCTL^{comm}$) are considered the most appropriate for use at the Site.

Although a detailed assessment of risks to groundwater is outside the scope of this report, it is considered appropriate to also screen against GAC for potential risks to the water environment on a precautionary basis. In line with earlier assessments (Amec Foster Wheeler 2016b, GHD 2020a), the Florida's CCTL for the protection of "*groundwater of Low Yield/Poor Quality*" ($CCTL^{GW}$) have been adopted. The CCTLs for such ground waters are generally higher (i.e. 10-times) than those for more sensitive groundwaters. According to Chapter 62-780 of the Florida Administrative Code (State of Florida, 2005), 'Poor quality' means "*groundwater within the affected monitoring zone with background concentrations, as defined in subsection 62-780.200(3), F.A.C., that exceed any of Florida's Primary or Secondary Drinking Water Standards referenced in Chapter 62-550, F.A.C.*" and 'Low yield' means "*groundwater that is contained in an aquifer that has an average hydraulic conductivity of less than one foot per day, determined by performing slug tests or an equivalent method for determining hydraulic conductivity on a minimum of three monitoring wells in each affected monitoring zone; and a maximum yield of 80 gallons per day, determined by pumping a four-inch well screened across the cross-section of the plume, for a minimum of two hours*". Even in the absence of such yield measurements, given the brackish nature of the groundwater beneath the Site and lack of any nearby abstractions, the use of these criteria at the site would seem reasonable.

Consequently, where contaminant concentrations are available, risk screening has been undertaken using the lower, and therefore more stringent, of the CCTL for 'Commercial/Industrial' land uses ($CCTL^{comm}$) and the CCTL for "*groundwater of Low Yield/Poor Quality*" ($CCTL^{GW}$).

2.3.5.2 Ground gas and vapour risk assessment

The assessment of ground gases and vapours was conducted, where possible, in line with British Standard BS 8576:2013 (BSI, 2013). As no quantitative data relevant to the gas regime beneath the footprint of the ISWMS is available, this principally constitutes the development of a gas conceptual site model (gCSM), which includes consideration of the sources of ground gases and vapours in and around the Site, pathways for gas migration and the potential receptors.

Where gas emission data is available its evaluation has been undertaken using British Standard BS 8485 (BSI, 2019), which has superseded CIRIA C665 (S.A Wilson et al., 2007) and the Ground Gas Handbook (S Wilson et al., 2009).

Where ground vapours have been documented due regard has been given to C682 The VOCs Handbook (Baker et al., 2009).

2.3.6 Future baseline

The future baseline should take account of any changes that would occur in the absence of the Project going ahead. For example, any natural processes that would modify the current baseline during the equivalent period as the lifetime of the Project or any enacted changes in legislation or business practices at surrounding sites, which may reduce (or increase) their industrial emissions to the environment.

Where such unavoidable changes are identified in relation to the land quality assessment, these are reflected in suitable amendments to the current baselines in the relevant section of this report.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

2.3.7 Significance evaluation

Significance evaluation used a significance test to assess which of the identified potential effects are sufficiently serious to warrant additional mitigation during project planning. The conclusion that is made using the significance test is based upon professional judgement, with reference to the project description, and available information about:

– The magnitude and other characteristics of the potential changes that are expected to be caused by the proposed development;
– The sensitivity of receptors to these changes;
– The effects of these changes on relevant receptors; and
– The value of receptors (where relevant).

The generic approach taken to significance evaluation within this EIA is described in Section 4 of the ToR (Wood 2021). This uses a combination of professional judgement and a topic-specific significance evaluation methodology based on available documents and data.

Within this Land Quality Assessment, the significance of any given effect was assessed using Table 2. Magnitude and Value/Sensitivity scores are defined in Table 3 and Table 4, respectively. Significant effects are those identified as 'High. 'Medium' effects have the potential to be significant, and indeed they would normally be deemed to be significant, but there may be some exceptions depending on the environmental topic and the application of professional judgement.

Table 2 ***Classification of effects (after Table 5.24 in Wood 2021). This table is specifically for assessing the potential geotechnical and geoenvironmental effects identified within this Land Quality Assessment***

Magnitude	Value and Sensitivity of Receptor		
	High	**Medium**	**Low**
High	High	High	Medium
Medium	High	Medium	Medium
Low	Medium	Medium	Low
Negligible	Low	Low	Negligible

2.3.7.1 Value and sensitivity of receptor

The main receptors anticipated are human health and infrastructure (buildings and services etc.) (see Section 2.2). The criteria used to assess the value and sensitivity of these receptors in this Land Quality Assessment are shown in Table 3.

The ToR states that "*The sensitivity of human health receptors should generally be considered as high although it can be less sensitive with, for example, health and safety controls in industrial areas*". Consequently, within this assessment the sensitivity of on-site human health receptors (*i.e.,* Site staff, construction workers and visitors at the ISWMS) has been considered to be medium, while for off-site human health receptor (*i.e.,* surrounding residential, commercial/industrial, schools) it has been considered to be high.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 3 ***Definition of the sensitivity assessment criteria for receptors (after Table 5.22 in Wood 2021). This table is specifically for assessing the sensitivity of the land quality receptors.***

Activity	Example Receptor Definition
High	The environmental parameter is fragile, and an effect is likely to leave it in an altered state from which recovery would be difficult or impossible.
Medium	The parameter has a degree of adaptability and resilience and is likely to cope with the changes caused by an effect, although there may be some residual modification as a result.
Low	The parameter is adaptable and is resilient to change.

2.3.7.2 Magnitude

The general criteria used to assess the magnitude of each effect in this Land Quality Assessment are shown in Table 4. No relevant quantitative data was identified regarding soil and ground gas concentrations upon which a quantitative risk assessment could be based. In the absence of such data, uncertainty remains about if, and to what extent, soil contamination and the ground gas regime pose a risk at the Site. Consequently, in assigning magnitude assessment criteria to each potential soil quality and ground gas effects, professional judgement has been used to derive a magnitude score that considered both a likely 'worst case' consequence and the likelihood of such an event arising. For example, where the consequence could potentially be "high" but is considered unlikely or very unlikely to occur, a magnitude of "medium" or "low" were ascribed, respectively.

Table 4 ***Definition of the magnitude assessment criteria for any land quality effects (after Table 5.23 in Wood 2021).***

Activity	Example Receptor Definition
High	Short term, acute effect on human health affecting both site users and users of sites in the vicinity, arising from contamination on the proposed development site, or chronic damage to human health affecting users of both the site and other sites in the vicinity arising from contamination on the proposed development site. Catastrophic damage to buildings or property on the proposed development site arising from contamination or geotechnical risks.
Medium	Chronic damage to human health of users of the proposed development site. Significant damage to buildings or property from contamination or geotechnical risks.
Low	Non-permanent effects to human health e.g., short-term intermittent nuisance such as odours not hazardous to human health. Minor damage to buildings or property from contamination or geotechnical risks.
Negligible	Minimal economic or social uses. Repairable effects of damage to buildings, structures and services e.g., staining or discoloration of building materials.

2.4 Cumulative effects

The ToR (Wood, 2021) identified two potential future developments in the vicinity; the Planned Area Development for Camana Bay; and the proposed Cruise Berthing Facility.

However, due to the nature of geotechnical and geoenvironmental risks, which are unlikely to extend beyond the Site boundary, GHD do not consider that there are likely to be any cumulative effects on land quality due to these potential future developments and so not cumulative affects have been considered within this report.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

3. Current baseline: geotechnical

The most relevant geotechnical information available for the approximately 30 acre Site is presented in the APEC Report titled 'Grand Cayman Proposed Integrated Waste Management System, ReGen, Geotechnical Investigation and Report' dated July 2023 (included as Appendix B). A total of 42 geotechnical soundings were performed across the whole Site for this investigation (15 boreholes and 27 test pits). The geotechnical baseline presented hereafter is mainly based on the information provided in the APEC report.

3.1 Topography

According to the ToR (Wood, 2021):

- Site elevation ranges approximately between 7 and 20 ft above mean sea level.
- The surrounding land is mainly flat and low lying, with the exception of the GTLF, and, where developed, is formed from reclamation of former mangrove swamp.
- The GTLF North Mound is approximately 100 ft AMSL and the South Mound is approximately 40 ft AMSL.

3.2 Geology

The three islands, Grand Cayman, Cayman Brac, and Little Cayman are emergent peaks of the generally submerged Cayman Ridge that forms the southern margin of the North American Plate. The islands mainly comprise Pleistocene age cemented corals locally known as the Ironshore Formation overlying Oligocene-Miocene karstic dolomitised limestone Bluff Formation of unknown thickness that in turn overlies igneous granodiorite that forms the core of Cayman ridge.

A review of the APEC report shows that the subsurface stratigraphy at the Site within the normal influence zone of a building foundation likely comprises 4 stratigraphic units: 1) Man Made Deposits, 2) Organic peat, 3) Ironshore Formation (Marl) and 4) Karstic Limestone (Dolostone). These stratigraphic units are briefly described in the following subsections.

3.2.1 Man-made deposits

According to the APEC Report, the man made deposits at the Site consist of two types of materials 1) waste materials interbedded with marl layers (probably placed as daily cover) and are covered with a veneer of topsoil forming the existing ground surface, and 2) shot rock. The APEC test pit and borehole logs show that the waste and marl man made deposits are present in the central and eastern portion of the Site and range in thickness from 0.9 m (3 feet) to 4.9 m (16 feet), with thicker deposits generally encountered along the eastern portion and northern margin of the eastern half of the Site.

The western, junk yard, portion of the Site is generally covered with shot rock although waste material was also encountered at the location of Borehole B-15. The shot rock was approximately 2.4 m (8 feet) to 3.7 m (12 feet) thick.

Additionally, there is a small (approx. 1 acre) geomembrane lined and capped area in the eastern part of the GTLF, within the footprint of the proposed RWL. This area reportedly contains ash, a by-product of Hurricane Ivan timber waste that was burned. The ash is reported to have arsenic content arising from insecticides originally used to treat the timber. No construction records are available for this area but there are some marker posts indicating its position on the ground. The geoenvironmental impact of this containment cell is considered further in Section 8.3.1.

3.2.2 Organic Peat

The presence of a highly compressible organic material (peat) is reported at some locations, in particular in the central part of the site. This 0.3 m (1 foot) to 2.7 m (9 feet) thick layer is either present at the soil surface or mixed and buried

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

beneath the above-described man-made deposits. As reported by APEC (2021), deeper pockets of peat may be present at other locations on the site which may not be detected, if at all, until earthwork for the proposed development commences.

3.2.3 Ironshore Formation

According to Matley (1924, 1926) as reported in Jones (1994) late Pleistocene Ironshore Formation was initially colloquially referred to as the Ironshore due to its indurated calcrete crusted nature and presence along the shoreline, the term that is now used to identify these deposits across the Caymans. The Ironshore Formation was probably deposited in lagoonal, shoal, beach ridge, and reef settings, and is characterized by poorly consolidated friable limestone, calcarenites, and marl/calcite cemented oolitic limestone, when the sea level was approximately 120 m (400 feet) below the present sea level during the Ice Age. Oolitic limestone is made up of small spheres called ooiliths cemented together by lime mud. They form when calcium carbonate is deposited on the surface of sand-sized grains rolled (by waves) around on a shallow sea floor.

APEC (2021) borehole and test pit logs show that the Ironshore Formation extends to depths ranging from approximately 4 m (13.5 feet) to 6 m (20 feet) below ground level (bgl) corresponding to thicknesses of 1.8 m (6 feet) to 3.7 m (12 feet). According to the published geology, the Ironshore Formation encountered on the Island is up to 9 m (29 feet) thick.

Cavities are present in this Formation and typically found in a zone called *epikarst* and located at or near the interface with the Bluff Formation briefly described below.

3.2.4 Bluff Formation - Pedro Castle/ Cayman/ Brac Formations

The Ironshore Formation overlies the middle Oligocene to Pliocene Bluff Formation of karstic dolomitic limestone/ dolostone/ limestone lithologies, which are further subdivided into Pedro Castle Formation, Cayman Formation and Brac Formation in order of increasing depth (Jones 1994).

These formations are characterized by spectacular examples of filled and unfilled karst features[4]. Surficial karst is characterized by cavities and holes giving the Bluff Formation surface a honeycombed appearance. The presence of surficial karst at the Site is strongly indicated by relatively large cavities encountered directly below the Ironshore Formation ranging in depth from 0.9 m (3 feet) to 2.7 m (9 feet) bgl.

3.3 Groundwater table

Groundwater on the Site is globally at a depth ranging from 0.6 m (2 feet) to 1.4 m (4.5 feet) below the existing grades - corresponding to elevation 0 m AMSL. During Mean High Water Spring (MHWS) tide the groundwater elevation reaches higher elevation estimated to approximately 0.6 m (2.0 feet) AMSL.

3.4 Seismicity

3.4.1 Seismic site class

The Cayman Islands use the 2009 International Building Code (IBC), which in turn refers to ASCE 7 for Seismic Site classification.

ASCE 7 requires the assignment of a Seismic Site Class for calculations of earthquake design forces and the structural design based on a two percent probability of exceedance in 50 years. According to ASCE 7, the Seismic Site Class is a function of soil profile and is based on the average properties of the subsoil strata to a depth of 30 m

[4] Jones B, Smith D.S. (1988): Open and Filled Karst Features on the Cayman Islands: Implications for the Recognition of Paleokarst; Canadian Journal of Earth Sciences, 25, p1277 - 1291

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

(100 feet) below ground level. ASCE 7 provides the following three methods to obtain the average properties for the top 30 m (100 feet) of the subsoil strata:

– Average shear wave velocity
– Average Standard Penetration Test (SPT) N-values (uncorrected for overburden) or
– Average undrained shear strength

The APEC investigations extended to maximum depth of 7.9 m (26 feet) below the existing grades. The SPTs carried out in the Ironshore Formation are not considered representative due to the nature of materials being neither soil nor rock. Based on the criteria listed in Table 20.3.1 of ASCE7-16, and the discussion on local geology above, a Seismic Site Class 'C' can be used for preliminary design purposes pending shear wave velocity measurements.

According to APEC, the following Site coefficients can be used for design purposes.

Table 5 Seismic Coefficients (Source APEC)

Seismic Parameter	Coefficient
Short-period Site Coefficient F_a	1.136
Long-term Site coefficient F_v	1.5
Spectral response acceleration at short period S_{MS}	1.136 x 0.659 = 0.749g
Spectral response acceleration at period of 1 second S_{M1}	1.5 x 0.300 = 0.450g

3.4.2 Earthquakes

Grand Cayman is located on and along a fault line. A major 6.8 magnitude earthquake occurred on December 14, 2004, approximately 20 miles (32 km) south of Georgetown, without causing any damage on the island. A more recent 7.7 magnitude earthquake occurred on January 28, 2020 in the Cayman Islands area with its epicentre located farther and approximately 160 miles (250 km) from Grand Cayman.

A lack of strong events in Grand Cayman in the past 300 years could mean that seismic energy is accumulating in the fault and it may be released in the form of a large magnitude earthquake, estimated to be between Mw 7.2 and 7.5 based on the magnitudes of the three largest events over the past 100 years (Novelo-Casanova, 2010).

3.4.3 Liquefaction

No liquefiable soils are identified at or in the vicinity of the Site.

3.5 Slope stability

The Site is relatively flat, and no slope stability issues are expected.

3.6 Foundation recommendations

The existing waste and marl mix material is not considered suitable for foundation support. The proposed structures may potentially be founded either into the Ironshore Formation or into the Bluff Formation. However, due to the seismic design requirements, most of these structures would likely be required to be supported in the underlying karstic Bluff Limestone.

Different foundation types and site preparation techniques may be used for the construction of the proposed structures. The foundation type and corresponding site preparation to first consider will depend on the structure type (architecture and loads) and the depth of the bearing stratum in the footprint of this structure. The usable foundations features are presented and discussed later in Section 9.1.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

4. The George Town Landfill (GTLF)

Based on the available information, contamination within the proposed ISWMS footprint is most likely to be associated with historical waste activities at the GTLF, which is understood to be owned by CIG and operated by the Department of Environmental Health.

4.1 Historical development of the GTLF

Amec Foster Wheeler (2016a) summarised the history of the landfill largely based on an earlier report by Post Buckley Schuh & Jernigan. Observations made during site visits have also been reported by Amec Foster Wheeler (2016a, 2016c).

Amec Foster Wheeler (2016a) state that *"Waste disposal at the site began in the mid 1960's when GIS [sic] leased a 20 acre parcel of land. Canals and dykes were constructed to drain the site and the indigenous mangroves cleared. Some waste was placed below the water table in dredged areas 3 to 6 feet (0.9m – 1.8m) deep where marl was recovered to obtain fill for roads and as cover to the waste deposits. Up until around 1985 the volume of waste deposited in the landfill was reduced by burning. The old landfill area is therefore likely to comprise ash towards the base"*. GHD understand that this refers to the 'Old Landfill Area' shown in Figure 3. **All of the proposed ISWMS footprint, <u>except for Area 4 (Landfill Gas Facility),</u> appears to lie outside of the Old Landfill Area.**

The majority of the land within the current GTLF footprint, including the Main Landfill Area (Figure 3), was acquired in 1989. It "i*s characterized by a mound rising to 77 ft. (23.6 m) above mean sea level (MSL) and was formed by tipping over an area of former mangrove swamp which was partially excavated to recover the underlying marls (calcareous soils)*" *(*Amec Foster Wheeler, 2016c). In 1989, landfill operations involved *"placing and compacting the solid waste with heavy equipment and covering the waste with soil on a daily basis. The cover soil is generally marl excavated from on-site sources, or supplied by a contractor from off-site sources" (*Amec Foster Wheeler, 2016a). Elsewhere, Amec Foster Wheeler (2016a) confirm that since ~1990 the limestone of the Ironshore Formation[5] has also been excavated to a depth of 14 ft (4.2 m) below the water table for use as daily cover *(*Amec Foster Wheeler, 2016a). In 1991, further land to the south was acquired giving the current total area of ~73 acres or ~30 hectares *(*Amec Foster Wheeler, 2016a, 2016c). The majority of the GTLF site is likely to have received some degree of waste materials (Amec Foster Wheeler, 2016c), with the exception of the outlying extremities to the west of the highway and to the north of the North Canal (Figure 3). **All of the proposed ISWMS footprint appears to lie outside of the Main Landfill Area.**

The Cayman Islands were heavily impacted by Hurricane Ivan in September 2004 and the GTLF was the ultimate destination for much of the cleanup debris. Amec Foster Wheeler (2016a) reported that *"A flat lying area in the north-western part of the site has largely been infilled with demolition and related wastes from the disaster clean-up operations following Hurricane Ivan in 2004. It originally comprised areas of open water arising from previous marl abstraction".* There is some confusion and uncertainty regarding the exact location and boundaries of this, and other, areas within the GTLF and various names have been used for them in different reports. Figure 3 suggests that the 'Hurricane Ivan Fill Area' (HIFA) extends over most of the land to the west of the Main Landfill Area, but Figure 4 (which is assumed to be based on subsequent clarification of waste locations) suggests that wastes were only deposited in the northern half of the HIFA shown in Figure 3. Based on the apparent infilling of a marl extraction pit (water filled) between 2004 and 2005 (Figure 8 A and B), it seems likely that Hurricane Ivan debris was used to infill this excavation and that the HIFA is limited to that indicated in Figure 4 rather than Figure 3. **All of the proposed ISWMS footprint appears to lie outside of the HIFA.**

The area immediately to the south of the HIFA is not labelled on Figure 4, but Amec Foster Wheeler (2016a, 2016c) reported that during site visits in 2014-2015, scrap metal and tyres were stockpiled in this area. Consequently, within this report we have referred to this area as the 'Old Scrap and Tyre Stockpile Area" (OSTSA). **Apart from parts Area**

[5] The Ironshore formation (Cayman Islands) has marl sediment in some places and coral type limestone elsewhere

To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

1 (Residual Waste Landfill and Hydrated Lime and Bottom Ash Storage Areas), most of the proposed ISWMS footprint appears to lie predominantly outside of the OSTSA.

Amec Foster Wheeler (2016a) also reported that *"An arsenic contaminated waste containment pit, which comprises a small geomembrane lined and capped area; is located in the eastern part of the Hurricane Ivan in-fill. Amec Foster Wheeler understands that this contains ash from the burning of treated timber waste arising from the post Hurricane Ivan clean up. The ash is reported to have a high arsenic content due the insectides/fungicides [sic] originally used to treat the timber. No construction records were made available for this area but there are some marker posts indicating its position which were observed on the ground".* Different documents refer to this pit by a variety of names; in Figure 3 it is labelled as the 'Arsenic Containment Pit', and in Figure 4 as the 'Arsenic Fill Site'. Within this report, we have adopted the term "Arsenic Containment Cell".

Figure 4 also shows the anticipated expansion of the Main Landfill Area on to the "NW Extension Area" in order to accommodate wastes received prior to the completion of the ISWMS. **The Arsenic Containment Cell will lie within the ISWMS footprint (Area 1) and will be located beneath the proposed Residual Waste Landfill.**

To the south of the Arsenic Containment Cell areas lies the 'Equipment Storage Area' (ESA) (Figure 3). In relation to this area, Amec Foster Wheeler (2016c) reported that "*Both operational and redundant site plant is stored on a flat stoned area in the southern part of the site. The operational plant includes excavators, a refuse compactor and hook lift trucks. Skips and shipping containers are also stored in this area. There are a number of steel sheeted buildings used variously for the storage of materials (e.g. aluminium cans), the storage of equipment (e.g. a bailer) and for plant maintenance*". Figure 4 refers to these buildings as the "Recycling Compound".

Also in this area, both Figure 3 and Figure 4 identifies an 'Oil and Hazardous Waste Storage Area' (OHWSA) but there is a discrepancy in the exact location of this facility between the two. Amec Foster Wheeler (2016c) noted that this area consisted of:

– *"A waste oil storage area. Waste oils and fuels are stored within a concrete surfaced and bunded hard standing where they are tested and segregated before being pumped into larger shipping tanks prior to export for subsequent off-island recycling or treatment;*
– *Covered and fenced hazardous waste storage compound. This is used for the storage of hazardous waste such as paints and household chemicals. These are subsequently transferred off-island for treatment/disposal; and*
– *On site laboratory used for the testing of waste oils and chemicals delivered to the site"*.

The majority of Area 1 coincides with the ESA and OHWSA, but most of the other areas of the proposed ISWMS footprint appear to lie outside of these areas.

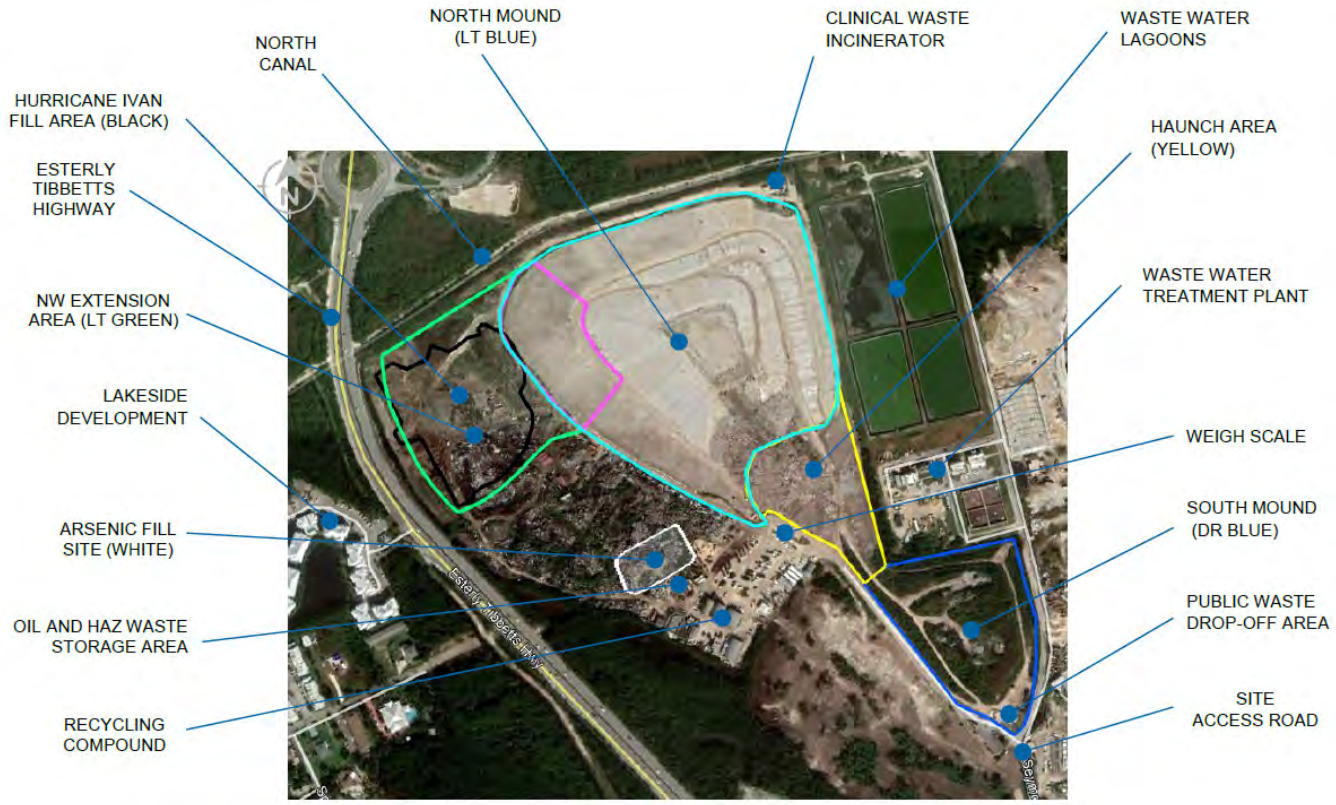

Figure 4 *Layout of the Georgetown Landfill according to GHD (2021b)*

4.2 Current leachate emissions

The GTLF may represent an offsite source of contamination that could affect the ISWMS. GHD is not aware of any relevant soil concentration data but monitoring for CIG (EHL, 2020) includes sampling leachate taken from a "*Ditch at west side of working face*" (Figure 5), which we assume to be indicative of the potential runoff that may reach the ISWMS. However, it is assumed that such migration will be reduced once the GTLF has been closed and restored.

EHL (2020) present metal concentration data for 2016-2020 (Box 1), which demonstrate that both arsenic and chromium consistently exceed Florida cleanup standards for groundwater. Such temporal trends were not presented for other parameters, but data for the leachate sample analysed in 2020 are summarised in Table 6. These values are substantially higher than corresponding data for ground and surface water samples.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. Table 6 Summary of analytical data (excluding metals) for a leachate sample collected in 2020 (EHL, 2020)

Analyte	Concentration	Analyte	Concentration
Biological oxygen demand (BOD)	**<MDL**	Petroleum Hydrocarbons*	**<MDL**
Chemical oxygen demand (COD)	1300 mg/L	Total Organic Carbon (TOC)	470 mg/L
Nitrate - nitrite	16 mg/L	Acetone	9.7 µg/L
Nitrite	11 mg/L	Phenol	3.0 µg/L
Total Kjeldahl Nitrogen	490 mg/L	Toluene	1.0 µg/L
Total Nitrogen	510 mg/L	Ethylbenzene	0.54 µg/L
Total Phosphorus	1.9 mg/L	Xylene	0.82 µg/L
pH	8.1	Naphthalene	2.0 µg/L
Sulphate	5.5 mg/L	Endosulphan 1	0.042 µg/L
Ammonia	350 mg/L	Delta BHC	0.025 µg/L
Unionised ammonia	25 mg/L	Faecal Coliform bacteria	69100 mpn/100 ml
Total hardness	1800 mg/L		

Notes: MDL=Method Detection Limit; Petroleum hydrocarbons were analysed using the Total Petroleum Hydrocarbon Criteria Working Group (TPHCWG) method

4.3 Current gas and vapour emissions

Although a landfill gas extraction system is proposed to feed into the ISWMS, GHD is not aware of any contemporary landfill gas monitoring. Amec Foster Wheeler (2016b) stated that no historical gas monitoring data exists but presented monitoring from six "*gas probes*" (GP1-GP6) and three surface flux boxes in and around the main landfill mass (Figure 6).

The "*gas probes*" generally showed emissions typical of landfill gas (~50-60% methane, ~25-45% carbon dioxide and ≤2% oxygen). More detailed laboratory analysis of these gases generally showed an absence of carbon monoxide, ethane, ethylene, propane and propene at any location; hydrogen was only detected at a single location. Hydrogen sulphide was present at all locations (0.46-2,300 ppm). A number of non-methane volatile organic compounds (NMVOC) were present at more than three of the locations including:

– 1,2,4-Trimethylbenzene
– 1,3,5-Trimethylbenzene
– 2-Butanone (MEK)
– Acetone
– Benzene
– Carbon disulphide
– Ethylbenzene
– *m, p* and *o*-Xylenes
– Methylene Chloride
– Styrene
– Toluene

However, a single round of flux box measurements showed no detectable methane emissions from the landfill surface.

Further surveys, including monitoring of GP1, occurred in September 2016 by Amec Foster Wheeler (2017a) and in April 2018 by Wood (2018). However, GP1 is located in older wastes and methane concentrations equivalent to <1%

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

v/v were recorded on both occasions. These surveys included monitoring the surface emission of methane; the results of the most recent survey is presented in Figure 7, but this is outside of the proposed ISWMS footprint.

Due to the unlined nature of the GTLF, subsurface lateral migration of landfill gases and vapours from the landfill does represent a potential risk to the ISWMS but given the elevated nature of much of the GTLF, the distance between the active (North Mound) area of the GTLF and ISWMS facilities, the existing and planned installation of an active gas management system within the North Mound of the GTLF and the presence of the RWL between the North Mound and the remainder of the ISWMS facilities, the likelihood of any meaningful subsurface migration from the GTLF to the ISWMS facilities is considered to be minimal.

Figure 6 Location of the "gas probes" installed by Amec Foster Wheeler (2016b)

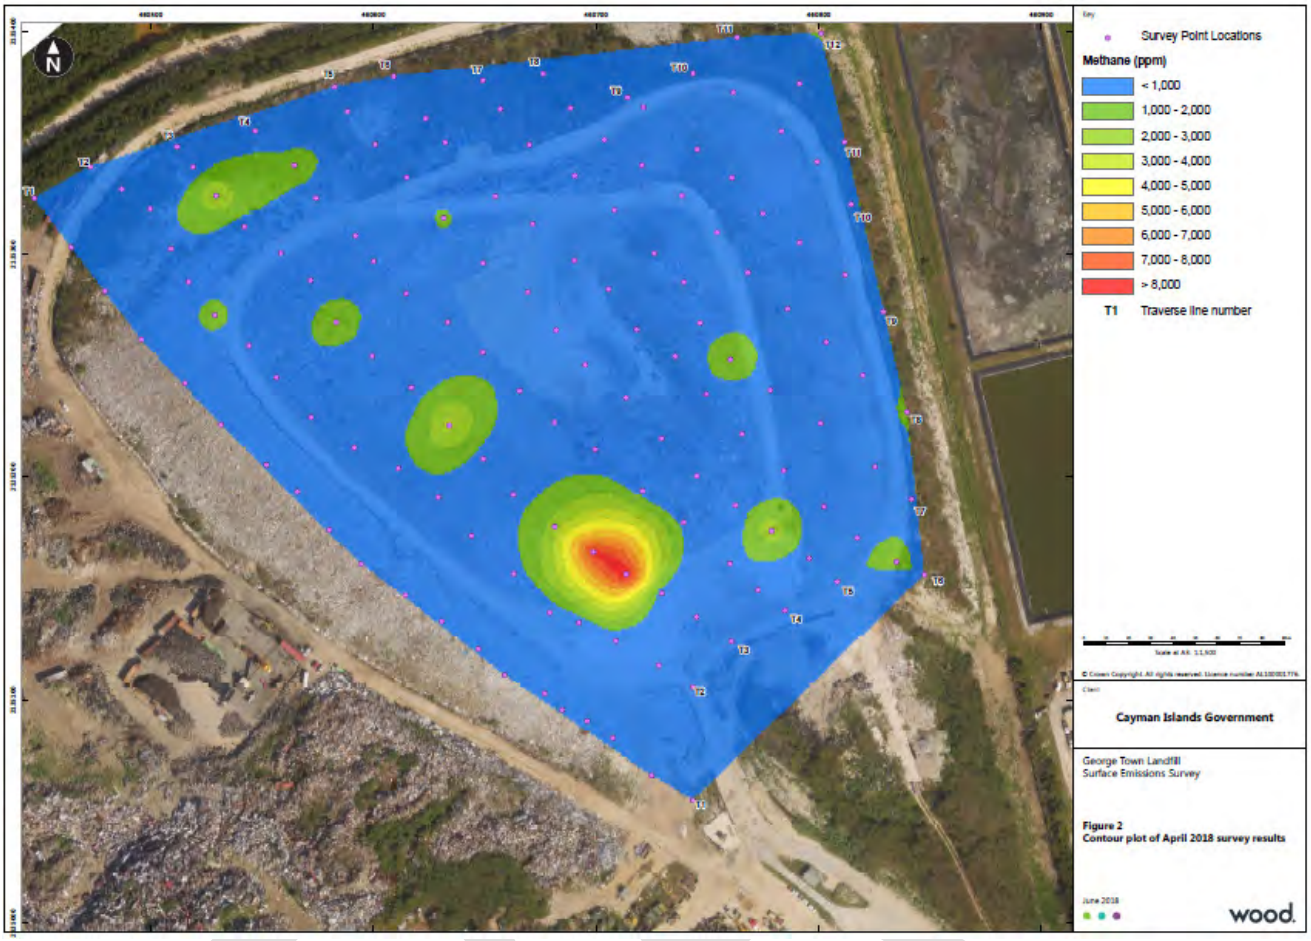

Figure 7 ***Results of a survey of methane surface emissions at the main landfill area of the Georgetown Landfill (After Figure 2 in Wood, 2018)***

4.4 Future of the GTLF

The waste management strategy for the Islands (Amec Foster Wheeler, 2016c) outlined the inadequacies and non-sustainability of contemporary waste management practices on each island, including the GTLF on Grand Cayman.

The current GTLF generally operates on outdated 'dilute and disperse' principles and lacks most environmental mitigations commonly applied to modern landfill facilities in the US and UK. For example, Cardno ENTRIX (2013) report that it lacks "*a basal liner, leachate collection and disposal system, and master stormwater treatment and disposal system".* As a result, leachate emissions have been "*identified by local regulators as one of the main sources of contamination to North Sound"* (Cardno ENTRIX, 2013) and Amec Foster Wheeler (2016c) identified this as a substantial driver for the ISWMS development.

The waste management strategy (Amec Foster Wheeler, 2016c) anticipates the closure of the GTLF but states that it "*is expected to continue to be in operation while the new Integrated Solid Waste Management System is developed and implemented through the procurement and construction of alternative waste management facilities. During this time the footprint of the site will continue to expand*".

A number of options for the remediation and restoration of the GTLF have been proposed (Amec Foster Wheeler, 2016c), including landfill mining and capping options. A review of these options (GHD, 2021b) concluded "*that a landfill cap with an active landfill gas management system is required to be provided over the North Mound to reduce its impact on the surrounding environment, but is not required for the older, less active South Mound*".

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

As part of the pre-commencement works on the ISWMS project, the northern half of the North Mound (Phase 1) has already been capped and that landfill gas extraction wells have been installed (Appendix A). Extraction of gas from these wells will supply, in part, the Landfill Gas Facility as part of the ISWMS. However, landfilling will continue to expand westwards (Phase 2) while the ISWMS is constructed, before this area is also capped and gas extraction installed (Appendix A) leading up to and immediately following commencement of the ISWMS operations.

5. Current baseline: geoenvironmental

5.1 Satellite imagery timeline

Satellite imagery presented within Google Earth Pro (Figure 8) suggests that the entire ISWMS site was undeveloped and heavily vegetated prior to September 2004, with the exception of small areas along the margins of the Site that were already utilised as roadways and compounds associated with the adjacent GTLF. The site has been progressively cleared from the north since this time.

– The northern third of the site was initially cleared between September 2004 and November 2005, presumably in the aftermath of Hurricane Ivan (see Section 4.1). The Hurricane Ivan Fill Area, OSTSA and Arsenic Containment Pit (see Section 4.1) are clearly visible by November 2005.
– The land immediately to the south of this was cleared and excavated between December 2005 and February 2007, when ponds and open water is present in this area. This was presumably to provide daily cover for the landfill (see Section 4.1).
– However, this area had been infilled and levelled by March 2008 when the ‘Equipment Storage Area’ (see Section 4.1) begins to be evident. The OHWSA (see Section 4.1) has been added by March 2013.
– The remainder of the Site remains undeveloped and heavily vegetated until 2020-21 when extensive site clearance, but no development, becomes evident.

5.2 Known or potential sources of contamination

Based on the available information, contamination within the proposed ISWMS footprint is most likely to be associated with historic waste treatment and disposal activities including those at the GTLF. However, the risks from such contamination is likely to vary at different areas of the ISWMS.

The known or potential sources of contamination associated with each area of the Site are outlined below.

5.2.1 Area 1

As discussed in Section 0, it seems likely that disposal of Hurricane Ivan debris was limited to the HIFA, which is outside the footprint Area 1. However, the disposal of wastes beneath this area prior to 2004 cannot be discounted.

Based on the currently proposed master plan (Figure 1) it is assumed that the footprint of Area 1 will include some or all of the following potential sources of contamination. The potential contaminants that may be anticipated are summarised in Table 7.

5.2.1.1 Old Scrap and Tyre Stockpile Area (OSTSA)

Satellite imagery from 2005 and 2007 (Figure 8) clearly shows apparent mounds of a grey material within the OSTSA. Such mounds are less distinct in subsequent images and it is unclear if these mounds are scrap/tyres or remaining hurricane debris. However, Wood (2016a, 2016c) have reported that during site visits in 2014-2015, scrap metal and tyres were stockpiled in this area (Figure 9). Consequently, it seems unlikely, but possible, that wastes (including hurricane debris) are present beneath the OSTSA.

GHD has not been provided with a full description of the source and nature of the scrap metal stored in the OSTSA, nor of any depollution process applied prior to stockpiling. So it is possible that the stockpiles may have contaminated the underlying ground.

Figure 9 *Storage of scrap metals and tyres presumed to be at the Old Scrap and Tyre Stockpile Area (After Figure 3.11 in Wood 2016c)*

5.2.1.2 Arsenic containment cell

The damage caused by Hurricane Ivan resulted in large amounts of debris, which included natural vegetation and wooden timber. It is understood that this was collected together at a number of Debris Sites around Grand Cayman (CIRO, 2005) and burnt and/or used to produce mulch. It is understood that the debris included timber treated with preservatives, including chromated copper arsenate (CCA). Subsequent analysis showed that the ash was not suitable to be left at the various debris sites or for reuse (CIRO, 2005).

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

GHD understands that the ash from all the Debris Sites (~4,133 cubic yards in total) was ultimately disposed of in a custom-built cell within the GTLF site. This is designated as the Arsenic Containment Pit in Figure 3, but elsewhere is referred by various names including the 'ash pit' or 'ash disposal cell' etc.; the term Arsenic Containment Cell has been adopted within this report. Design drawings suggest that it is:

– Built upon the underlying "solid rock" but surrounded by "existing waste";
– 100ft (30.5m) wide by 250ft (76.2m) long;
– Sunk to a depth of ~6ft below ground and is mounded to a height of ~12ft above ground;
– Enclosed (top and bottom) within an engineered containment system including drainage layer and composite liner;
– Covered in a seeding layer and grass.

It is assumed the cell contains leachate retained within the liner, but there is no current sampling or leachate recovery wells or system. GHD understands that it has also been suggested that arsine gas may be present within the cell.

5.2.1.3 Equipment storage area (including the OHWSA)

The timeline presented in Figure 8 clearly indicates that extraction activities (presumably borrow pits for the extraction of marl for daily cover at the GTLF) occurred in this area after 2005 but that surface levels had been reinstated prior to 2008. This required the infilling of the void areas. GHD is not aware of any details of the nature and source of these fill materials (i.e. potentially waste materials).

5.2.1.3.1 Equipment storage area

This area has a diverse usage, including the storage of current and redundant vehicles, plant and equipment, storage of certain separated waste streams and equipment maintenance.

5.2.1.3.2 Oil and Hazardous Waste Storage Area (OHWSA)

This area consists of two separate compounds; one for waste oils and fuels and one for hazardous waste (e.g., paints and household chemicals).

Amec Foster Wheeler (2016c) reported that ground water in a monitoring borehole MW16 between western canal and the Waste Oil Storage Area "*was seen to be visually contaminated with black oils*. The location of MW16 is shown in Figure 11. Amec Foster Wheeler (2016b) also quote the Department of Environmental Health (DEH) as stating "*significant hydrocarbon release occurred from the waste oil storage area in 2004 as a consequence of the tidal surge associated with Hurricane Ivan overtopping the containment bund*". This is understood to have contaminated the perimeter canal, which was subsequently remediated (Amec Foster Wheeler, 2016b).

Similar releases from the hazardous waste storage area may not have been visible and so cannot be excluded.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Figure 10 Bunded Waste Oil Storage Area at the GTLF (After Figure 3.2 in Amec Foster Wheeler, 2016c)

Figure 11 Location of groundwater monitoring wells at the GTLF (After Figure 1 in EHL 2020)

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 7 Summary of the potential sources and associated contaminants identified within, and adjacent to, the study area, which have been considered within this Land Quality Assessment

Area	Potential source	Potential contaminants
Within the study area		
Old Scrap and Tyre Stockpile Area	Any fill or buried wastes[a] (including hurricane debris)	• Metals • Combustion products, including polyaromatic hydrocarbons (PAHs) and dioxins • Asbestos • Landfill/Ground gases
	Subsequent waste storage[a] (including scrap and tyres)	• Metals • Hydrocarbons, including polyaromatic hydrocarbons (PAHs) • Asbestos
Arsenic Containment Cell	Ash material within the cell.	• Metals, especially arsenic and chromium and copper • Combustion products, including polyaromatic hydrocarbons (PAHs) and dioxins • Asbestos • Arsine gas
Equipment Storage Area	Any fill materials (including wastes)[a]	• Metals • Combustion products, including polyaromatic hydrocarbons (PAHs) and dioxins • Asbestos • Landfill/Ground gases
	Storage of vehicles, plant and equipment	• Metals • Hydrocarbons, including polyaromatic hydrocarbons (PAHs)
	Maintenance activities.	• Metals • Hydrocarbons, including polyaromatic hydrocarbons (PAHs) • Paints and solvents etc.
Oil and Hazardous Waste Storage Area	Any fill materials (including wastes)[a]	• Metals • Combustion products, including polyaromatic hydrocarbons (PAHs) and dioxins • Asbestos • Ground gases
	Waste oil store	• Hydrocarbons, including polyaromatic hydrocarbons (PAHs) • Organic vapours
	Hazardous waste store	• Hydrocarbons, including polyaromatic hydrocarbons (PAHs) • Paints and solvents etc. • Pesticides • Polychlorinated biphenyls (PCBs) • Organic vapours

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Area	Potential source	Potential contaminants
Adjacent offsite areas		
Georgetown Landfill	Landfilled wastes	• Leachate • Landfill/Ground gases • Organic vapours
Notes: [a] the potential composition of such wastes has not been determine and so the range of likely contaminants cannot be delineated with any degree of certainty.		

5.2.2 Area 2

Based on the currently proposed master plan (Figure 1) it is assumed that the footprint of Area 2 lies outside the boundary of the existing GTLF. Satellite imagery (Figure 8) suggests that this area remained heavily vegetated until late 2020/early 2021 when Area 2 was cleared of vegetation. However, a limited geotechnical site investigation of this area was undertaken in November and December 2020 (APEC, 2021). This identified "*Topsoil 'Marl' fill and municipal waste mix*" present at multiple locations across Area 2. APEC (2021) report that "*Aerial imagery indicates the area was used as a landfill sometime between the 1970s and 1980s. The 1994 aerial photography shows the site as being covered. This is consistent with an environmental assessment report prepared in 1991 by Post, Buckley, Schuh and Jernigan Inc. (PBSJ) which refers to landfilled waste on an adjacent property not owned by CI Government*".

The available information indicates that, while undeveloped, historical waste disposal did occur in this area before it was overgrown with vegetation. The nature, volume and extent of wastes present, and contamination associated with it, is not known. Equally, the gas generation potential of such wastes remains uncertain, but is expected to be minimal due to the age of the waste.

5.2.3 Area 3

The proposed location of the CUC substation is isolated from all other ISWMS components and lies to the north beyond the North Canal (Figure 1). The timeline presented in Figure 8 clearly indicates this area remained vegetated and undisturbed until at least 2021. Consequently, contamination is not anticipated in this area, although the disposal of wastes beneath this area prior to 2004 cannot be completely discounted.

5.2.4 Area 4

The proposed location of the Landfill Gas Facility (LGF) is isolated from all other ISWMS components and lies adjacent to the current wastewater treatment plant. The LGF lies within the footprint of the "Old Landfill" Figure 3 or "South Mound" Figure 4. The "Old Landfill" is believed to have been reduced by burning and so is "*likely to comprise ash towards the base"* (Section 0). Consequently, some level of contamination is expected in this area, but GHD is not aware of any site investigation data that presents data relating to the ground conditions and contaminant concentrations.

5.2.5 Sources of contamination - baseline conclusions

The entire ISWMS footprint, with the possible exception of Area 3, is known or suspected to be on land affected by landfill or waste disposal activities. In addition to any geotechnical hazards posed by potential buried wastes, it is possible that contamination may be encountered, but the significance of such contamination cannot be determined in the absence of suitable and sufficient soil analysis data (Section 5.3.6). In addition to any buried wastes, Area 1 is known to have been affected by releases from the OHWSA and potentially other activities in this area.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

5.3 Available soil analysis data

Although a substantial amount of ground and surface water data (including limited amounts of sediment sampling) are available for the GTLF site, little or no soil analysis data is available relevant to the proposed footprint of the ISWMS. For example, the APEC (2021) geotechnical report describes site investigation activities but no soil analysis or ground gas measurement was undertaken.

5.3.1 Area 1

Amec Foster Wheeler (2016b) describe limited soil monitoring conducted by CIG-DEH (the "DEH Data") who collected samples "*from surface soils adjacent to some of the MW monitoring point locations. Forty datasets are available for the period 2011-2013*". Three of these samples were from within Area 1 and a further four relate to the HIFA and, while not directly relevant to Area 1 may be indicative of similar conditions (Table 8). All the available analysis data for these locations are presented in Table 10 for inorganic contaminants, Table 11 for PCBs and Table 12 for various pesticides. The relevance of this data and any other data to each area of the Site is discussed below.

Table 8 Locations at which surface soil samples have been collected by DEH. Each location has been allocated to the relevant part of the Site. Locations that are within the likely footprint of the ISWMS are highlighted in bold

Location	Part of Site	Location	Part of Site
SW1	(Location unknown)	**MW9**	**HIFA (outside ISWMS)**
SW2	Main landfill area	**MW9 B**	**HIFA (outside ISWMS)**
SW3	**HIFA (outside ISWMS)**	MW10	Old landfill
SW7	(Location unknown)	MW11	Main landfill area
SW12	**Hazardous waste storage Area**	MW12	Main landfill area
Drain 1	(Location unknown)	MW13	Old landfill
Drain 2	(Location unknown)	**MW14**	**Arsenic containment cell and OSTSA**
MW1	(Location unknown)	**MW15**	**Arsenic containment cell and OSTSA**
MW1 B	(Location unknown)	**MW17**	**HIFA (outside ISWMS)**
MW5	Main landfill area	MW18	Main landfill area
MW8	Main landfill area		

5.3.1.1 Old Scrap and Tyre Stockpile Area (OSTSA)

The soils at the OSTSA are poorly characterised. However, all the DEH surface soil data presented in Table 10, Table 11 and Table 12 are relevant to the OSTSA except for that for SW12. This includes four locations from the HIFA located further north and outside the footprint of Area 1 (Table 8).

With respect to inorganic contaminants, Table 10 suggests that there are no substantial risks to human health or ground water from the current surface soils in this area. The exceedances of the $CCTL^{comm}$ for arsenic mainly relate to results apparently subject to inexplicably high MDLs. Only one sample above the relevant MDL marginally exceeds the $CCTL^{comm}$ (see Section 5.3.5).

PCBs (7 congeners only) were not detected above the MDL in any sample (Table 11). However, the MDLs used were all more than an order of magnitude greater than the $CCTL^{comm}$, meaning that no conclusions can be drawn regarding PCB risks in relation to the surface soils in this area.

Samples were also tested for a range of pesticides (Table 12). The only pesticide detected above the relevant MDL was endrin (2 samples only) and the concentrations detected did not exceed the $CCTL^{GW}$. However, the MDLs for 9 of the pesticides exceeded the relevant CCTL and so no conclusions can be drawn regarding these compounds in surface soils in this area.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

In addition to the DEH data, Amec Foster Wheeler (2016b) reports that "*Seventeen samples of surface soil were collected from across the Hurricane Ivan fill area[6] for asbestos analysis. No asbestos was detected in any of the samples*".

It should be noted that this surface sampling does not demonstrate that contamination (including asbestos) is not present within any underlying fill/wastes.

5.3.1.2 Arsenic containment cell

The cell contains ash from the burning of Hurricane Ivan debris at various sites across the Grand Cayman. Prior to disposal, sampling of ash from several sites found that the mean arsenic concentration was 65.4 mg/kg (n=13) and as a result was not suitable to be left or reused (CIRO, 2005). The ash analysis data is presented in Table 9.

In addition to total concentrations, leachability was also determined as TCLP (SW-846 Test Method 1311: Toxicity Characteristic Leaching Procedure) and SPLP (SW-846 Test Method 1312: Synthetic Precipitation Leaching Procedure). The mean leachate concentration of arsenic was 0.24 mg/l (n=13) and 0.03 mg/l (n=2), respectively (CIRO, 2005).

Table 9 ***Concentrations (mg/kg) of various metals in samples of ash created by the burning of Hurricane Ivan debris at various sites on Grand Cayman (CIRO, 2005). The mean and standard deviation for each metal is also shown.***

Apart from this pre-disposal data, the material in the Arsenic Containment Cell is poorly characterised. However, the surface soil data for MW14 and MW15 (Table 10, Table 11 and Table 12) is relevant to the characterisation of the surface soils in this area .

[6] This is assumed to include the OSTSA.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

With respect to inorganic contaminants, the available data (Table 10) suggest that there are no substantial risks to human health or ground water from the current surface soils in this area. The exceedances of the $CCTL^{comm}$ for arsenic in this area relate to results apparently subject to inexplicably high MDLs (see Section 5.3.5).

The 7 PCB congeners analysed were not detected above the MDL in any sample (Table 11). However, the MDLs used were all more than an order of magnitude greater than the $CCTL^{comm}$, meaning that no conclusions can be drawn regarding PCB risks in relation to the surface soils in this area.

Samples were also tested for a range of pesticides (Table 12). The only pesticide detected above the relevant MDL was endrin (1 samples only) and the concentrations detected did not exceed the $CCTL^{GW}$. However, the MDLs for 9 of the pesticides exceeded the relevant CCTL and so no conclusions can be drawn regarding these compounds in surface soils in this area.

It should be noted that this surface sampling does not demonstrate that contamination (including asbestos) is not present within the ash within the cell, but we understand that current plans involve constructing the RWL over the existing cell, and so the ash will not be disturbed or exposed.

5.3.1.3 Equipment storage area (including the OHWSA)

Although oil contamination has been observed in the vicinity of the Waste Oil storage Area (Section 5.2.1.3), the soil in this area is poorly characterised. The only available data relevant to this area is for surface soil samples collected from SW12 (Table 10, Table 11 and Table 12).

With respect to inorganic contaminants, the available data (Table 10) suggests that there are no substantial risks to human health or ground water from the current surface soils in this area. The exceedances of the $CCTL^{comm}$ for arsenic in this area relate to results apparently subject to inexplicably high MDLs (see Section 5.3.5).

The 7 PCB congeners analysed were not detected above the MDL in any sample (Table 11). However, the MDLs used were all more than an order of magnitude greater than the $CCTL^{comm}$, meaning that no conclusions can be drawn regarding PCB risks in relation to the surface soils in this area.

Samples were also tested for a range of pesticides (Table 12). No pesticides were detected above the relevant MDL in this area. However, the MDLs for 9 of the pesticides exceeded the relevant CCTL and so no conclusions can be drawn these compounds in surface soils in this area.

It should be noted that this surface sampling does not demonstrate that contamination (including asbestos) is not present below the surface in this area.

5.3.2 Area 2

No soil quality data was identified in relation to Area 2.

5.3.3 Area 3

No soil quality data was identified in relation to Area 3.

5.3.4 Area 4

No soil quality data was identified in relation to Area 4.

5.3.5 Background arsenic concentrations

Arsenic occurs naturally in soils at varying concentrations in different geographic regions and, in some areas, natural concentrations can exceed risk-based assessment criteria where such background concentrations have not been considered in the derivation of such criteria.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Little information has been identified in the scientific literature regarding the levels of naturally-occurring arsenic in the Cayman Islands. The only information identified is in an ICENS (2015) report, but we are aware that additional studies have been conducted. ICENS (2015) reported that background arsenic concentrations "*ranged from 11 to 85 µg/g (median, 28.8 µg/g;* mean *38.6 µg/g*)", but it is unclear on how many samples this is based on.

As 1 ug/g is equivalent to 1 mg/kg, this suggests that most Cayman soils will exceed the $CCTL_{Comm}$ for arsenic of 12 mg/kg (Florida DoEP, 2005). It should be noted that the CCTL are derived using a target lifetime excess cancer risk level of 1.0E-6 and the value for arsenic assumes a bioaccessibility of 0.33. In any future risk assessment in relation to arsenic in soils, this background concentration and the applicability of the CCTL for arsenic for use in the Cayman Islands should be considered.

5.3.6 Soil analysis – baseline conclusions

Minimal and poor quality soil analysis data is available with respect to Area 1. The data available does not suggest that substantial contamination will be encountered in this area but there remains considerable uncertainty.

No data has been identified relating to Areas 2, 3 and 4 and so no conclusions can be supported with respect to the levels of soil contamination that may be present in these areas, the risks these represent, nor the need for any mitigation measures.

5.4 Available gas data

Although gas data is available for the adjacent GTLF, no specific data relevant to the ISWMS site (Areas 1,2,3 or 4) has been identified.

No historical gas monitoring data for the GTLF is available prior to 2015 (Amec Foster Wheeler, 2016b) but subsequent gas monitoring has been undertaken. Amec Foster Wheeler (2016b) describes six "*gas probes*", one of which (GP6) is very close to the OSTSA (Figure 6) and could indicate the potential for gas migration towards Areas 1 and 2. However, Amec Foster Wheeler (2016b) only present summary monitoring data (Section 4.3) and it is not possible to establish the gas fluxes measured in GP6 specifically. Further monitoring of the landfill mound was also undertaken in September 2016 by Amec Foster Wheeler (2017a) and in April 2018 by Wood (2018). However, access to GP6 was obstructed on both occasions and no monitoring was possible.

The results of the latest methane surface emission survey (Figure 7) suggest that the emissions outside of the main GTLF will be low (<1% methane) but this does not mean that subsurface migration cannot occur. As noted in Section 4.3, the likelihood of any meaningful migration from the GTLF to the ISWMS facilities is considered to be minimal.

5.4.1 Gas data – baseline conclusions

The GTLF is known to be generating landfill gas and, given the absence of a basal liner, lateral migration of gases from the GTLF could affect the ISWMS. However, the likelihood of any meaningful subsurface migration from the GTLF to the ISWMS facilities is considered to be minimal.

Given that the North Canal, which is likely to prevent lateral gas migration, appears to lie between the GTLF and Area 3, this area is considered unlikely to be affected by ground gases.

Area 4 is to be located on the 'Old Landfill' to the south of the GTLF. No gas data relevant to this area has been identified. However, it is assumed that the gas generation potential of any buried wastes in this area will be minimal and that the landfill gas facility (Area 4) will be designed to be intrinsically safe and to be minimally staffed, and so the risks are likely to be minimal.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

5.5 Future baseline

No factors were identified that, in the absence of the Project proceeding, would materially alter the baseline conditions outlined above. Changes to the management practices at the GTLF could conceivably increase or decrease the potential for landfill gas migration on to the ISWMS site, but, again, the likelihood of any meaningful migration from the GTLF to the ISWMS facilities is considered to be minimal.

DRAFT

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

6. Conceptual site model (CSM)

BS EN ISO 21365 defines a Conceptual Site Model (CSM) as a "*synthesis of all relevant information about a potentially contaminated site with interpretation as necessary and recognition of uncertainties. The description relies on the concept, of "source-migration pathway-receptor linkages" (sometimes termed «contaminant linkages») that are, or might be, present.*"

6.1 Land contamination (CSM)

This CSM relates to the ISWMS as a whole (Areas 1, 2 and 4 only[7]) and summarises the identified potential pollutant linkages, which each consist of a source/contaminant, pathway and receptor.

The receptors relevant to this assessment are identified in Section 2.2. The potential sources of contamination identified with respect to Area 1 (Table 7) are assumed to also be relevant to Areas 2 and 3. The potential pathways considered to be relevant to this assessment are:

1. Direct ingestion of soils and dusts; and / or
2. Inhalation of soil-derived dusts by individuals while outdoors; and / or
3. Inhalation of tracked-back soil-derived dust in onsite buildings; and / or
4. Direct contact with buildings, building materials and infrastructure; and / or
5. Contaminant migration due to surcharging of historic arsenic waste pit with new RWL; and / or
6. Contaminant migration via windblown dust, flooding or surface runoff.

The consumption of tainted food produce (including fruit, vegetables, meat and other animal products) is not considered a viable pathway at a waste treatment and disposal facility, as it is assumed that no such produce will be farmed on-site.

It should be noted that the assessment of risks to ground and surface waters is outside the scope of this assessment and so the related pathways have not been listed.

Gases and vapours are considered in Section 6.2.

Table 13 Potential pollutant linkages relevant to non-gaseous contaminants displayed as a matrix showing the pathways (referenced by number) that link each contaminant with the various receptors.

	Site staff, construction workers and visitors (human health)	ISWMS infrastructure	Surrounding land users e.g. residential, commercial/industrial, schools (human health)
Metals including arsenic	1,2,3,5	4	2, 5
Polyaromatic hydrocarbons (PAHs)	1,2,3,5	4	2, 5
Dioxins etc.	1,2,3,5	4	2, 5
Asbestos	2,3,5	4	2, 5
Hydrocarbons (including fuels)	1,2,3,5	4	2, 5
Polychlorinated Biphenyls (PCBs)	1,2,3,5	4	2, 5

[7] The current information suggests that land contamination is unlikely to affect Area 3 as it has apparently not been used for waste disposal operations and is isolated from gas migrating from the GTLF.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

	Site staff, construction workers and visitors (human health)	ISWMS infrastructure	Surrounding land users e.g. residential, commercial/industrial, schools (human health)
Pesticides	1,2,3,5	4	2, 5
Paints and solvents	1,2,3,5	4	2, 5

6.2 Ground gas and vapours (gCSM)

There are two principal sources of ground gases; migration from main GTLF to Areas 1, 2 and 4[8] and gas generated in the underlying naturally occurring soils (i.e., “peat”) or any anthropogenic wastes and made ground *etc.* Risk relating to gas generation within the underlying calcareous strata is considered unlikely and has not been considered.

As outlined in Section 4, the GTLF is primarily a landraise with only limited amounts of wastes below ground level. This, together with the shallow groundwater table (Section 3.3), will limit any lateral migration to the surface (approx. 3.3 ft (1 m) bgl) soils. Although landfill gas can dissolve and migrate within groundwater, this is considered unlikely to occur to a significant extent given the configuration of the GTLF. Lateral gas migration is only likely to be of concern where pressure-driven advective flow occurs but, again, as described in Section 4.3, the likelihood of any meaningful migration from the GTLF to the ISWMS facilities is considered to be minimal; being mitigated by the landfill gas collection system **(Appendix A)** already installed at the currently capped North Mound (Phase 1) and to be installed the ongoing westward expansion (Phase 2), along with the presence of the lined and capped RWL between the GTLF and the remainder of the ISWMS facilities.

With respect to gas generation immediately beneath Areas 1, 2, 3 and 4:

– Area 1 is the RWL and landfill gas generated in this area is unlikely to be of concern;
– There is some evidence of buried wastes in Area 2 but these are understood to be historical and of limited depth and so the gas generation potential of these materials is assumed to be low;
– There is currently no evidence of any materials likely to generate gas beneath Area 3; and
– Although Area 3 is the location of the “old landfill” and so buried wastes are anticipated it is understood that these wastes were generally burnt prior to burial and so their gas generation potential is considered to be low.

T

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

7. Impact assessment: geotechnical

The likely significant land quality effects related to the geotechnical environment identified both in the ToR and during the assessment are provided in Table 14.

Table 14 Likely significant land quality effects (Geotechnical) that are recommended for assessment

Activity	Effect	Receptor
All phases (construction, operation and decommissioning) – site activities	Existing waste surface layer, which is not suitable to support the proposed development.	ISWMS infrastructure
All phases (construction, operation and decommissioning) - Site activities	Karst features in subsurface such as sinkholes and caves that are unable to adequately support the proposed development leading to geotechnical instability.	Site staff, construction workers and visitors (human health) ISWMS infrastructure
All phases (construction, operation and decommissioning) - seismic/tectonic events	The Cayman Islands sit in an active seismic zone. Earthquakes and tsunamis are significant potential hazards.	Site staff, construction workers and visitors (human health) ISWMS infrastructure

7.1 Impact assessment

The geotechnical hazards can be listed in the following order in terms of their economic impact on the proposed development starting from less severe to most severe.

1. Waste layer, which is deemed unsuitable for support of the proposed development.
2. The Bluff Formation limestone or alternatively improved ground are considered the only suitable foundation supporting stratum.
3. The location of the Site in a high seismic zone.

All three of the above geotechnical hazards have been assessed in the absence of mitigation, as provided in Table 15.

Table 15 Assessment of potential geotechnical effects in relation to the ISWMS

Activity	Receptor	Sensitivity	Magnitude	Significance	Rationale
Development	**ISWMS infrastructure**	**Medium**	**Medium**	**Medium**	**The waste layer has a low bearing capacity. This is considered a Significant Effect.**
Construction on shallow foundations on Ironshore Formation	**Site staff, construction workers and visitors (human health)**	**Medium**	**Medium**	**Medium**	**Geotechnical instability could pose a risk to all on-site persons. This is considered a Significant Effect.**
	ISWMS infrastructure	**Medium**	**Medium**	**Medium**	**Shallow cavities in Ironshore Formation may result in foundation collapse. This is considered a Significant Effect.**
Construction of piled foundations in bedrock of the	**Site staff, construction workers and visitors (human health)**	**Medium**	**Medium**	**Medium**	**Geotechnical instability could pose a risk to all on-site persons. This is considered a Significant Effect.**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Activity	Receptor	Sensitivity	Magnitude	Significance	Rationale

Operation of facility	**Site staff, construction workers and visitors (human health)**	**Medium**	**High**	**High**	**Cayman island seismicity could damage new structures, which could pose a risk to all on-site persons. This is considered a Significant Effect.**
	ISWMS infrastructure	**Medium**	**High**	**High**	**Cayman island seismicity could damage new structures. This is considered a Significant Effect.**

Notes: All potentially significant effects are highlighted in bold

7.2 Summary of findings

As identified in Table 15, potentially significant impacts related to the ground conditions and geological setting of Grand Cayman have been identified in the absence of appropriate mitigation. As discussed in Section 9.1, these potentially significant impacts can be reasonably mitigated for the ISWMS Site.

8. Impact assessment: geoenvironmental

8.1 Imported fill

GHD are aware that fill (e.g., soils or aggregates) will need to be imported during the construction of ISWMS, particularly to Area 3.

In many countries, importing recycled soils and aggregates (*e.g.* crushed concrete and demolition arisings) can represent sources of new contamination at development sites. Recycled aggregate, in particular, can be contaminated with asbestos where all asbestos-containing materials were not removed prior to demolition.

However, GHD have been informed by ReGen that any imported aggregates will be of virgin quarried stone as recycled aggregate is not currently available on the island. Indeed, one of the objectives of ISWMS is to establish a market for recycled secondary aggregate on the island as a more sustainable alternative to quarried stone. GHD also assume that any imported soils will also be uncontaminated and suitable for their intended use.

Consequently, it has been assumed that any imported fill will not pose any contamination risks and so such sources have not been considered within this impact assessment. Notwithstanding the above, it is recommended that the construction phase plan include suitable sampling and testing requirements for all imported soils and aggregates to provide auditable evidence of their quality and suitability.

8.2 Embedded measures

The currently proposed layout, design and operation of the ISWMS is described elsewhere (GHD, 2023) and appears to have already taken some consideration of potential land contamination risks, explicitly or otherwise. Some of these proposed mitigation measures are outlined in more detail in the sections below.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

8.2.1 Area 1

Area 1 coincides with a number of known potential sources of contamination and is at greatest risk from gas migration associated with the adjacent GTLF but, in general, also represents the least sensitive uses assuming that the residual waste landfill and other open air storage areas have minimal above ground buildings or structures with enclosed unventilated voids in which gases may accumulate.

8.2.1.1 Medical Waste Facility

According to Chapter 4, "*The Medical Waste Facility will be constructed to receive, store and process medical waste, and occasional other wastes such as expired currency and confiscated illicit drugs and other combustible materials not suited for treatment at the ERF*". The Medical Waste Facility building will be open sided with a roof to protect the equipment beneath, which will help to mitigate any potential landfill gas risks.

8.2.1.2 Residual Waste Landfill (RWL)

According to Chapter 4, "t*he RWL will be an engineered facility with a composite liner, leachate containment, leachate treatment, environmental controls and monitoring*". It will be designed, constructed and/or operated in line with relevant modern US standards, which should include procedures to manage leachate, dusts, odours and landfill gas, such as:

- Resource Conservation and Recovery Act (RCRA) (Sub-Title D Non-Hazardous Rules and Sub-Title C Hazardous Rules)
- RCRA Subtitle D (258) Seismic Design Guidance for Municipal Solid Waste Landfill Facilities.
- 40 Code of Federal Regulations
  - Part 258 – Criteria for Municipal Solid Waste Landfills
  - Part 264 – Standards for Owners and Operators of Hazardous Waste Treatment, Storage, and Disposal Facilities
  - Part 265 – Interim Status Standards for Owners and Operators of Hazardous Waste Treatment, Storage, And Disposal Facilities
- Standards for the GTLF design (remediated as part of the ISWMS project):
  - Florida Administrative Code No. 62-701.500: Landfill Operation Requirements
  - Florida Administrative Code No. 62-701.600: Landfill Final Closure

The nature of the residual waste (principally post-combustion residues from the ERF) will limit its leachability and putrescibility but, if fully complied with, such standards will further ensure that any leachate or landfill gas emissions are appropriately mitigated.

8.2.2 Area 2

Area 2 represents probably the most sensitive land uses at the ISWMS, including administration and maintenance buildings and public access areas. However, it is also located farther from the GTLF than Area 1 and so is shielded to a greater or lesser degree from any potential leachate or gas migration. However, although satellite imagery suggest Area 2 may be previously undeveloped, virgin land, initial investigations (APEC, 2021) suggest some degree of earlier waste disposal may be present in this area.

8.2.2.1 Energy Recovery Facility (ERF)

According to Chapter 4, "t*he ERF will be a state of the art controlled combustion (mass burn) facility that will render combustible, non recyclable waste to an inert ash and reduce the volume of incoming waste by 90 percent*":

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

– "*Advanced air pollution control (APC) and continuous emissions monitoring (CEM) systems will ensure that ERF emissions are able meet current and future standards and not pose an adverse effect to the environment*" minimising the risks from any aerial deposition.
– The ERF will generate two residual waste streams; bottom ash (Section 8.1.2.4) and air pollution control residues (APCR); "*The bottom ash will be managed via the proposed Bottom Ash Recycling Facility. The APCR and boiler ash will be stabilised with cement and / or pozzolan by means of a pan mixer at the ERF and thereafter discharged to a concrete mixer truck for transfer to and disposal at the proposed RWL"*.
– It is anticipated that cooling will use abstracted groundwater "*from an array of three 425 ft deep borehole wells beneath the ISWMS Site. Once passed (non-contact) through the condensers, the 'spent' cooling water will then be returned to groundwater using a further array of three 725 ft deep discharge wells.*" This arrangement, involving physically separated primary and secondary cooling circuits, minimises the risk of the released cooling water being contaminated.

8.2.2.2 Green Waste Processing Facility

According to Chapter 4, the facility "*will receive and process source segregated Yard Waste and will store the resulting compost and mulch products for onward resale into the Cayman marketplace*" and will operate to recognised standards (*i.e.*, Resale secondary Yard Waste materials – Florida Administrative Code FAC 62 709.550). Achieving such standards should necessitate adequate quality control procedures with respect to the contamination of the received green wastes.

8.2.2.3 Construction and Demolition Waste Processing Facility

According to Chapter 4, processing "*allow for the recycling, recovery and diversion of construction and demolition wastes into aggregates, scrap metals and combustible material (using a shredder for bulky materials) for energy production in the ERF*". It will be located away from sensitive receptors but no relevant environmental controls are specified. It will be designed, constructed and/or operated in line with relevant modern standards.

8.2.2.4 Bottom Ash Processing Facility

According to Chapter 4, "*The Bottom Ash (BA) Processing Facility will be designed to process bottom ash from the ERF into a recovered aggregate which is suitable for use on the Cayman Islands and recovered ferrous and non ferrous metals that can be recycled through overseas markets for those materials*". The facility will be enclosed to provide complete containment to reduce dust emissions during operations. It will be designed, constructed and/or operated in line with relevant modern standards.

8.2.2.5 Abandoned and End of Life / Scrap Metal Processing Facility

According to Chapter 4, the facility will "*allow for the recycling, recovery and diversion of vehicles that have been abandoned or surpassed their useful life, as well as the processing of bulky scrap metals*". ELVs "*will be received, inspected, stripped of batteries, catalytic converters, airbags, tyres, etc. before being depolluted of all coolants, oils, and fuels to allow the recyclable components of the vehicles to be separated for re-use*". It will be designed, constructed and/or operated in line with relevant modern standards.

8.2.2.6 Materials Recycling Facility (MRF)

According to Chapter 4, the facility will "*be constructed to allow for the diversion and recovery of dry mixed recyclables (DMR) from Contract Waste in Grand Cayman and the Sister Islands; receiving, processing, baling and/or storing DMR for onward resale into local and off island recycling markets*". An indoor area will allow storage of baled "weather-sensitive DMR (e.g. baled paper and card, or UV sensitive baled plastic)", all other materials will be stored in bales outside or in shipping containers.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

8.2.2.7 Household Waste Recycling Centre (HWRC)

According to Chapter 4, this will be "*the public's central drop-off point for recyclable/non-recyclable household waste, including specialist waste items such as hazardous household wastes*" and will "*comprise two distinct areas: a covered, single level re-use centre and an open, split level recycling centre close to the Project Site main entrance*". The HWRC will be fully concreted.

8.2.3 Area 3

Area 3 consists solely of the **CUC substation**. According to Chapter 4, this "*will be a pre-fabricated building(s) with specialized switchgear for connecting to the grid"* and "*The typical occupancy will be 1-2 people for monitoring and service"*. Area 3 will also require the importation of fill materials to provide adequate flood protection and vehicle access.

Area 3 is located to the north of the North Canal, which should isolate it from any contaminant or gas migration from the GTLF. Furthermore, this area is not suspected to have been subject to previous contaminative activities (e.g. waste disposal activities), although no data exists to confirm this.

8.2.4 Area 4

Area 4 consists solely of the **Landfill Gas Facility (LFG)**. According to Chapter 4, the LGF "*will be constructed to allow for the capture and destruction of LFG from the North Mound of the GTLF*" and "*Landfill gas will be extracted from the GTLF using a conventional gas extraction system of vertical wells bored into the landfill site, operating under slight negative pressure*". Depending on the location and design of the extraction system, the LGF should reduce or eliminate the potential for gas migration from the GTLF affecting other elements of the ISWMS. It will be designed, constructed and/or operated in line with Florida Administrative Code No. 62 701.530: Gas Management Systems.

The currently proposed gas collection system for the currently capped North Mound (Phase 1) and the ongoing Western Expansion (Phase 2) is presented in Appendix A. This shows the location of each extraction well and an estimate of their zone of influence. The design suggests that negative pressure could be established within the deepest areas of waste, but that this may not extend to the shallower sloping sides of the landfill, including those adjacent to Area 1.

8.2.5 Construction Environmental Management Plan (CEMP)

According to Chapter 4, a CEMP will be prepared prior to any construction activities. This will define the specific environmental mitigation measures to be applied in order to demonstrate application of the relevant pollution prevention Legislation and Good Industry Practice.

It is currently intended that:

– The use of locally available material in construction will be maximized (including C&D waste).
– Extents of the existing arsenic pit will be carefully defined and marked out and thereafter prepared to receive the overlying RWL.

It should be noted that, prior to construction, further geotechnical investigations and surveys are scheduled in order to "*provide detailed geological and geotechnical information for layers of made ground (which will be used mainly for road design), peat and unconsolidated limestone and characteristics of the underlying Dolostone bedrock (which will be used mainly for foundation design)*". It is recommended that these investigations also consider the nature and extent of any contamination and, in particular, the gas generation and migration potential of any underlying madeground (including buried wastes).

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

8.3 Potential risk management options

Until suitable and sufficient site investigation data is available regarding the levels of soil contamination present, the need for, and specification of, any risk management options (*i.e.* remediation) cannot be ascertained. However, given the nature of the development it is likely that substantial concentrations of contamination would need to be present before any risks would be considered unacceptable (*i.e.* remediation warranted)[8]. This is likely to limit the possibility and scope of any remediation required.

If risk management is required, an options appraisal exercise will be needed to identify the most appropriate remediation option or combination of options. The selection of the wide-range of potential options will depend on a variety of factors, including:

- Cost (including on-island availability);
- Available time-scale
- Nature of the contamination:
  - Organic or inorganic (including biodegradability)
  - Gross or light contamination
  - Localised or wide-spread.
- Nature of the receptor(s) at risks:
  - human health or infrastructure[9]
  - on-site or offsite

However, given the pollutant linkages outlined in the CSM (Section 6) and the low sensitivity of the development, it is likely that relatively low-risk and low-complexity remediation options would be appropriate. For example:

- Most risks to construction workers could probably be addressed by avoiding disturbance of heavily contaminated areas or, where necessary, adopting appropriate occupational hygiene practices (*e.g.* suitable welfare facilities, appropriate PPE and, if needed, respiratory protection).
- Most risks to site staff and visitors (i.*e.* on-site human health) and surrounding land users (i.*e.* off-site human health) could probably be addressed through targeted excavation to a limited depth and disposal in the RWL, changes to the layout of hardstanding and building footprints to avoid or cover the contamination and/or application of a layer of clean capping (*i.e.* soils, aggregates or hardstanding).
- Most risks to “ISWMS infrastructure” could probably be addressed by modifying its design/specification (*e.g.* specifying contaminant-resistant concrete for in-ground structures, or contaminant resistant drinking water pipe materials).
- Risks to from ground gases and vapours would be limited to internal voids and spaces within buildings and structures and could probably be addressed through adequate consideration during foundation design (*e.g.* specifying naturally or mechanically ventilated sub-slab voids, gas and vapour membranes within foundations and/or gas alarms).

8.4 Impact assessment

Due to the current unsustainable design and practices at the GTLF and resulting effects on soil (and groundwater) quality, it is likely that the construction of the ISWMS will result in net environmental benefits. However, there is the potential for shorter-term land contamination effects during the construction, operation and residual effects following the ultimate decommissioning of the ISWMS. These effects have been assessed in the following sections.

[8] In addition to any requirement to mitigate harmful effects from contamination, remediation could also be required for aesthetic (*e.g.* odour) or geotechnical reasons.

[9] The need for soil remediation could also be driven by risks to ground or surface waters, but such risks are considered elsewhere.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

The potential for land contamination (metals, PAHs and possibly dioxins *etc.*) to arise as a result of unintentional fires associated with the storage of combustible wastes at various parts of the ISWMS has not been considered. The risk of such fires, together with the proposed mitigation measures, has been considered in Chapter 4 of the EIA.

8.4.1 Area 1

Area 1 is adjacent to the GTLF and represents the current location of the OSTSA, Arsenic Containment Cell, Equipment Storage Area and OHWSA, which are potential sources of contamination. The potential land quality effects of the proposed development on the relevant receptors (Section 2.2) identified during this assessment are summarised in Table 16 and the significance of these is assessed in Table 17.

Table 16 ***Potential geoenvironmental effects identified in relation to Area 1. This area is primarily the proposed as the location of the Residual Waste Landfill (RWL), but also the Bottom ash storage and Medical waste facilities.***

Activity	Effect	Receptor
Construction Phase		
Disturbance, exposure and spread of existing contamination (including buried wastes) within the Old Scrap and Tyre Stockpile Area	Exposure (and potential spread) of contaminated soils at the site surface and release of runoff, dusts, gases and vapours	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope of this report and discussed elsewhere)
Disturbance of existing contamination within the Arsenic Containment Cell (current plans involve constructing the RWL over the existing cell and so disturbance should be minimised)	Exposure (and potential spread) of contaminated soils at the site surface and release of runoff, dusts, gases and vapour	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)
Disturbance of existing contamination within the Equipment Storage Area, particularly the Oil and Hazardous Waste Storage Area (*NB*: oil contamination has been observed in this area)	Exposure (and potential spread) of contaminated soils at the site surface and release of runoff, dusts, gases and vapour	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)
Construction involving composite liner and capping	Impervious footprint has the potential to modify the current gas migration regime, increasing gas migration.	• Surrounding land users (human health) e.g. residential, commercial/industrial, schools
Operational Phase		
Spillage or release of wastes during storage, transport or placement prior to capping	Exposure (and potential spread) of contaminated soils at the site surface and release of runoff, dusts, gases and vapour	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Activity	Effect	Receptor
Failure of landfill cap (*e.g.* due to flawed engineering, extreme weather events or sea-level rise)	Ingress of rainwater resulting in uncontrolled releases of leachate to the surrounding ground, and the escape of any accumulated gases and vapours	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)
Failure of the composite liner (*e.g.* due to flawed engineering, extreme weather events or sea-level rise)	Ingress of groundwater and uncontrolled releases of leachate and contaminants to the surrounding ground	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)
Medical waste incinerator is anticipated to be diesel-fired	Leaks and spillages from the diesel storage and distribution system could affect the underlying soils (and ground water)	• Site staff, construction workers and visitors (human health) • ISWMS infrastructure • (ground and surface water is outside scope)
Storage and maturation of ERF Bottom ash	Release of contaminants in leachate and dusts leading to contamination of local soils	• Site staff, construction workers and visitors (human health) • (ground and surface water is outside scope)
Inappropriate disposal of additional wastes during emergency situations (*e.g.* hurricane or earthquake debris)	The composition of such wastes is unknown but may result in unsuitable materials being interred that could result in unforeseen leachate and gas/vapour issues that could affect the surrounding ground	• Site staff, construction workers and visitors (human health) • ISWMS infrastructure • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)

Notes: 1. No distinction has been made between the construction, operation and decommissioning phases of the RWL, as the construction and operation of a landfill occur concurrently and the landfill is not intended to be decommissioned, although it will be capped, restored and managed in the long-term.

Table 17 Significance assessment of potential geoenvironmental effects in relation to Area 1. All potentially significant effects are highlighted in bold.

Activity	Receptor	Sensitivity	Magnitude	Significance	Rationale
Disturbance, exposure and spread of existing contamination (including buried wastes) within the Old Scrap and Tyre Stockpile Area	**Site staff, construction workers and visitors (human health)**	**Medium**	**Medium**	**Medium**	**Depending on the contaminants encountered the consequences could be substantial (e.g. asbestos or other carcinogens), but this is not likely to occur. However, some risks (particularly to construction workers) may require some degree of mitigation (Section 8.2). Until suitable and sufficient site investigation data is available, this is considered a potential Significant Effect**
	Surrounding land users (human health) e.g. residential, commercial/industrial, schools	High	Negligible	Low	The low contaminant mobility likely to be associated with such weathered wastes, mean it is very unlikely that off-site effects will occur that are greater than those to on-site receptors. Considered not to be significant.
Disturbance of existing contamination within the Arsenic Containment Cell (current plans involve constructing the RWL over the existing cell and so disturbance should be minimised)	Site staff, construction workers and visitors (human health)	Medium	Medium	Medium	Arsenic, and chromium, (which are both potentially carcinogenic) are known to be present but no disturbance of these materials is proposed. Considered not to be significant.
	Surrounding land users (human health) e.g. residential, commercial/industrial, schools	High	Low	Medium	It is very unlikely that off-site effects will occur that are greater than those to on-site receptors. Considered not to be significant.
Disturbance of existing contamination within the Equipment Storage Area, particularly the Oil and Hazardous Waste Storage Area (NB oil contamination has been observed in this area)	**Site staff, construction workers and visitors (human health)**	**Medium**	**Low**	**Medium**	**Oil contamination is known to exist and will need to be addressed. Although serious health effects are considered unlikely, some risks (particularly to construction workers) may require some degree of mitigation (Section 8.2). Until suitable and sufficient site investigation data is available, this is considered a potential Significant Effect**
	Surrounding land users (human health) e.g. residential, commercial/industrial, schools	High	Low	Medium	There have been no reported off-site affects from the currently identified oil contamination. It is unlikely that any off-site effects will occur if all on-site receptors are protected. Considered not to be significant.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Activity	Receptor	Sensitivity	Magnitude	Significance	Rationale
Construction involving composite liner and capping may modify the landfill gas migration	Surrounding land users (human health) e.g. residential, commercial/industrial, schools	High	Low	Medium	The likelihood of landfill gas migration to Area 1 from the GTLF is considered to be minimal. It is considered unlikely that gas risks to surrounding properties would be increased. Considered not to be significant.
Spillage or release of wastes during storage, transport or placement prior to capping	Site staff, construction workers and visitors (human health)	Medium	Medium	Medium	Some minor releases are likely during the 25 year operation. However, the operational standards are likely to ensure that only suitable materials are placed in the landfill and that any exposure of onsite workers is controlled. Considered not to be significant due to these inherent controls
	Surrounding land users (human health) e.g. residential, commercial/industrial, schools	High	Low	Medium	The relatively inert nature of the materials to be landfilled and the existing controls (which should include dust management), should mean that there is no significant risk to the health of off-site receptors.
Failure of landfill cap (*e.g.* due to flawed engineering, extreme weather events or sea-level rise)	Site staff, construction workers and visitors (human health)	Medium	Low	Medium	The relatively inert nature of the materials to be landfilled (solidified APCR etc.) should minimise the risk from leachable or volatile contaminants. The proposed construction standards should ensure that the cap is robust and installed to the required standard, and this EIA will consider potential Climate Change effects. Not considered significant
	Surrounding land users (human health) e.g. residential, commercial/industrial, schools	**High**	**Medium**	**High**	**The spread of landfill wastes could have serious affects over a large area. Although serious health effects are considered unlikely, some risks (particularly to construction workers) may require some degree of mitigation (Section 8.2). Until suitable and sufficient site investigation data is available, this is considered a potential Significant Effect**
Failure of the composite liner (*e.g.* due to flawed engineering, extreme weather events or sea-level rise)	Site staff, construction workers and visitors (human health)	Medium	Low	Medium	The relatively inert nature of the materials to be landfilled (solidified APCR etc.) should minimise the risk from leachable or volatile contaminants. The proposed construction standards should ensure that the cap is robust and installed to the required standard, and this EIA will consider potential Climate Change effects. Not considered significant.
	Surrounding land users (human health) e.g. residential,	High	Low	Medium	Given the nature of the proposed landfill contents, any resulting leachate is unlikely to pose any serious off-site risks. Not considered significant

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Activity	Receptor	Sensitivity	Magnitude	Significance	Rationale
	commercial/industrial, schools				
Medical waste incinerator is anticipated to be diesel-fired (leaks)	Site staff, construction workers and visitors (human health)	Low	Low	Low	Release of limited volumes of relatively low toxicity fuels are unlikely to be significant at a waste management facility and there is unlikely to be any critical ISWMS infrastructure in Area 1 that may be affected (e.g. drinking water pipes)
	ISWMS infrastructure	Low	Low	Low	
Storage and maturation of ERF Bottom ash	Site staff, construction workers and visitors (human health)	Low	Low	Low	Significant affects are considered unlikely given the nature of the activities in Area 1
Inappropriate disposal of additional wastes during emergency situations (*e.g.* hurricane or earthquake debris	Site staff, construction workers and visitors (human health)	Medium	Low	Medium	Although such an event is foreseeable during the ISWMS operational period, it is not certain. Substantial affects were not reported following the uncontrolled burial of Hurricane Ivan debris. The landfill construction and existing occupational health controls etc. should prevent or minimise any onsite exposures. Not considered Significant
	Surrounding land users (human health) e.g. residential, commercial/industrial, schools	High	Low	Medium	Although possible, given the landfill construction, it is unlikely that sufficient leachate or gases would be released to substantially affect any of the ISWMS infrastructure on Area 2 and could easily be detected via subsequent monitoring. Not considered significant.

8.4.2 Area 2

The potential land quality effects of the proposed development on the relevant receptors (Section 2.2) identified during this assessment are summarised in Table 18 and the significance of these is assessed in Table 19.

Historically, waste incinerators are known to have been associated with downwind land contamination as a result of atmospheric deposition, including dioxins and heavy metals. However, according to Chapter 4 the design of the ERF is described as *"a state-of-the-art controlled combustion (mass burn) facility"* with "*Advanced air pollution control (APC) and continuous emissions monitoring (CEM) systems will ensure that ERF emissions are able meet current and future standards and not pose an adverse effect to the environment". Consequently, stack emissions from the ERF are been considered to be a potential operational source of land contamination.*

The potential for the handling of APC residues to generate hazardous dusts that could contaminate local soils or of inadequate stabilisation has also not been considered. This risk, together with the proposed mitigation measures, is assessed in Chapter 4.

Table 18 ***Potential geoenvironmental effects identified in relation to Area 2. There is some evidence that all or parts of this area may have been subject to historical waste disposal but is the proposed location for most other components of the ISWMS, including the Energy Recovery Facility.***

Activity	Effect	Receptor
Construction Phase		
Disturbance, exposure and spread of buried wastes and associated contamination	Exposure (and potential spread) of contaminated soils at the site surface and release of runoff, dusts, gases and vapours	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)
Releases and spillages of polluting materials and wastes during construction	Contamination of the underlying clean soils	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)
Foundation and piling activities	Creation of migration pathways, including for ground gas and vapour migration	• Site staff, construction workers and visitors (human health) • ISWMS infrastructure • (ground and surface water is outside scope)
Construction of building and hardstanding	Impervious footprint has the potential to modify the current gas migration regime, increasing offsite migration.	• Surrounding land users (human health) e.g. residential, commercial/industrial, schools

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. Activity	Effect	Receptor
Operational Phase		
Storage and treatment of wastes contaminated with hazardous materials (*e.g.* Energy Recovery Facility, Green Waste Facility, Construction and Demolition Waste Facility, End of Life Vehicle Facility, Materials Recycling Facility and Household Waste Recycling Centre)	Contamination of underlying soils by non-aqueous phase liquids (*e.g.* oils), soluble contaminates in leachate/runoff or accumulation of contaminated dusts	• Site staff, construction workers and visitors (human health) • ISWMS infrastructure • (ground and surface water is outside scope)
	Inadequate management of contaminated surface water runoff leading to contamination of nearby soils	• Site staff, construction workers and visitors (human health) • ISWMS infrastructure • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)
Storage and treatment of construction and demolition wastes contaminated with hazardous materials including asbestos-containing materials	Accumulation of contamination /asbestos fibres in underlying soils and potentially released and spread during treatment and onward during reuse as aggregate.	• Site staff, construction workers and visitors (human health) • ISWMS infrastructure • (ground and surface water is outside scope)
Vehicle and plant fuel storage It is anticipated that oil-based fuels will be stored on-site.	Leaks and spillages from fuel storage and distribution system could affect the underlying soils (and ground water)	• Site staff, construction workers and visitors (human health) • ISWMS infrastructure • (ground and surface water is outside scope)
Leachate and runoff from the windrows at the Green Waste facility	Leading to contamination (including pesticides) of the underlying and surrounding soils	• Site staff, construction workers and visitors (human health) • ISWMS infrastructure • (ground and surface water is outside scope)
Potential return of geothermal cooling water (non-contact)	Reinjection of contaminated cooling water leading to contamination of the soils surrounding the injection point/soakaway	• Site staff, construction workers and visitors (human health) • ISWMS infrastructure • (ground and surface water is outside scope)
Vehicle operation and on-site maintenance	Spillages and leaks of fuels, hydraulic fluids, coolants and waste oils *etc.* affecting underlying soils, particularly at maintenance and waste storage areas	• Site staff, construction workers and visitors (human health) • ISWMS infrastructure (ground and surface water is outside scope)
Flooding or inundation due to extreme weather events or sea-level rise	Spread of wastes and contamination in floodwater/runoff leading to affects on soils beneath Area 2 and surrounding land	• Site staff, construction workers and visitors (human health) • ISWMS infrastructure • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)

Table 19 Significance assessment of potential geoenvironmental effects in relation to Area 2. All potentially significant effects are highlighted in bold.

Activity	Effect	Receptor	Sensitivity	Magnitude	Significance	Rationale
Construction Phase						
Disturbance, exposure and spread of existing contamination (particularly buried wastes) in the underlying soils	Exposure (and potential spread) of contaminated soils at the site surface and release of runoff, dusts, gases and vapours	**Site staff, construction workers and visitors (human health)**	**Medium**	**Medium**	**Medium**	**Depending on the contaminants encountered the consequences could be substantial (e.g. asbestos or other carcinogens), but this is not likely to occur. However, some risks (particularly to construction workers) may require some degree of mitigation (Section 8.2). Until suitable and sufficient site investigation data is available, this is considered a potential Significant Effect**
		Surrounding land users (human health) e.g. residential, commercial/industrial, schools	High	Low	Medium	The poor contaminant mobility likely to be associated with such weathered wastes, mean it is very unlikely that off-site effects will occur that are greater than those to on-site receptors. Considered not to be significant
Releases and spillages of polluting materials and wastes during construction	Contamination of the underlying soils	Site staff, construction workers and visitors (human health)	Medium	Low	Medium	Some releases are likely but are unlikely to be sufficient in scale to be significant. Considered not to be significant
		Surrounding land users (human health) e.g. residential, commercial/industrial, schools	High	Low	Medium	It is less likely for there to be any effects for off-site receptors. Not considered significant

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Activity	Effect	Receptor	Sensitivity	Magnitude	Significance	Rationale
Foundation and piling activities	Creation of migration pathways, including for ground gas (e.g. from underlying alluvium and/or migration from GTLF) and vapour migration	Site staff, construction workers and visitors (human health)	Medium	Medium	Medium	While there is some uncertainty about the potential gas risk, it is likely that any migration from the GTLF will negligible and the gas generation potential of the underlying soils will be low. Based on the nature of the development, the gas risk is thus considered to be low and so is not considered a potentially Significant effect
		ISWMS infrastructure	Medium	Medium	Medium	While there is some uncertainty about the potential gas risk, it is likely that any migration from the GTLF will negligible and the gas generation potential of the underlying soils will be low. Based on the nature of the development, the gas risk is thus considered to be low and so is not considered a potentially Significant effect
Construction of building and hardstanding	Impervious footprint has the potential to modify the current gas migration regime, increasing offsite migration.	Surrounding land users (human health) e.g. residential, commercial/industrial, schools	High	Low	Medium	In the absence of adequate Site investigation data and gas risk assessment, it is possible that off-site gas migration from the GTLF could occur. However, due to the landfill gas extraction system, this is considered unlikely and so is not considered a potentially Significant effect
Operational Phase						
Storage and treatment of wastes contaminated with hazardous materials (*e.g.* Energy Recovery Facility, Green Waste Facility, Construction and Demolition Waste Facility, End of Life Vehicle Facility, Materials Recycling Facility and	Contamination of underlying soils by non-aqueous phase liquids (*e.g.* oils), soluble contaminates in leachate/runoff or accumulation of contaminated dusts	Site staff, construction workers and visitors (human health)	Medium	Medium	Medium	Although some hazardous materials may be stored and treated, these should be identified and managed using appropriate occupational controls etc. Not considered significant
		ISWMS infrastructure	Medium	Low	Medium	Although possible, any affects are unlikely to have serious affects on the function or safety of infrastructure. Not considered significant
	Inadequate management of contaminated	Site staff, construction workers and visitors (human health)	Medium	Low	Medium	Given existing occupational H&S controls, exposure via surface water runoff is unlikely to be of concern. Not considered significant

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Activity	Effect	Receptor	Sensitivity	Magnitude	Significance	Rationale
Household Waste Recycling Centre)	surface water runoff leading to contamination of nearby soils	ISWMS infrastructure	Medium	Low	Medium	Likely runoff concentrations are unlikely to have serious affects on the function or safety of infrastructure. Not considered significant
		Surrounding land users (human health) e.g. residential, commercial/industrial, schools	High	Low	Medium	If not sufficiently mitigated, contaminated runoff could affect more sensitive off-site receptors. In the absence of detailed drainage and runoff treatment plans, this is not considered a potential Significant Effect
Storage and treatment of construction and demolition wastes contaminated with hazardous materials including asbestos-containing materials	Accumulation of asbestos fibres in underlying soils and potentially released and spread during treatment and onward during reuse as aggregate.	**Site staff, construction workers and visitors (human health)**	**Medium**	**Low**	**Medium**	**Some C&D materials will contain asbestos and it is becoming apparent that they may also be tainted by other sorbed contaminants. Adequate control measures will be required (*e.g.* periodic testing and occupational hygiene monitoring). Considered a potential Significant Effect**
		ISWMS infrastructure	Medium	Negligible	Low	Compared to site staff, effects of infrastructure are likely to be negligible. Not considered significant
Vehicle and plant fuel storage	Leaks and spillages from fuel storage and distribution system could affect the underlying soils (and ground water)	Site staff, construction workers and visitors (human health)	Medium	Low	Medium	The volume of fuel stored is likely to be minimal and the health risks for diesel are not substantial. Not considered significant
		ISWMS infrastructure	Medium	Negligible	Low	Not considered significant
Leachate and runoff from irrigation of the windrows at the Green Waste facility	Leading to contamination (including pesticides) of the underlying and surrounding soils	Site staff, construction workers and visitors (human health)	Medium	Low	Medium	The leachate is unlikely to have substantial toxicity but due to the long-term operation, adequate consideration of leachate management is required. However, this is not considered a significant effect
		ISWMS infrastructure	Medium	Low	Medium	No substantial affects on infrastructure are anticipated. Not considered significant

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Activity	Effect	Receptor	Sensitivity	Magnitude	Significance	Rationale
Potential return of geothermal cooling water (non-contact)	Reinjection of contaminated cooling water leading to contamination of the soils surrounding the injection point/soakaway	Site staff, construction workers and visitors (human health)	Medium	Negligible	Low	"No contact" design minimises any risks. Not significant
		ISWMS infrastructure	Medium	Low	Medium	"No contact" design minimises any risks. Not significant
Vehicle operation and on-site maintenance	Spillages and leaks of fuels, hydraulic fluids, coolants and waste oils *etc.* affecting underlying soils, particularly at maintenance and waste storage areas	Site staff, construction workers and visitors (human health)	Medium	Low	Medium	Even if vehicle maintenance does occur on site, spillages should be minimal and volumes limited. Not significant
		ISWMS infrastructure	Medium	Low	Medium	No substantial affects on infrastructure are anticipated. Not considered significant
Flooding or inundation due to extreme weather events or sea-level rise	Spread of wastes and contamination in floodwater/runoff leading to affects on soils beneath Area 2 and surrounding land	Site staff, construction workers and visitors (human health)	Medium	Low	Medium	The likely affects are unlikely to substantially raise the existing risks from the working environment. Not considered significant
		ISWMS infrastructure	Medium	Low	Medium	Th contamination risks to infrastructure unlikely to affect function or safety. Not significant
		Surrounding land users (human health) e.g. residential, commercial/industrial, schools	**High**	**Medium**	**High**	**The spread of landfill wastes could have serious affects over a large area. Although serious health effects are considered unlikely, some risks (particularly to construction workers) may require some degree of mitigation (Section 8.2). Until suitable and sufficient site investigation data is available, this is considered a potential Significant Effect**

8.4.3 Area 3

The current information suggests that land contamination is unlikely to affect Area 3 as it has apparently not been used for waste disposal operations and is isolated from gas migrating from the GTLF. Thus, the potential land quality effects of the proposed development on the relevant receptors (Section 2.2) are limited to those summarised in Table 20 and the significance of these is assessed in Table 21.

Table 20 Potential geoenvironmental effects identified in relation to Area 3 (CUC substation). No underlying contamination or landfill gas migration is anticipated in this area.

Activity	Effect	Receptor
Construction Phase		
Releases and spillages of polluting materials and wastes during construction	Introducing new contamination, which may become mobile, resulting in contaminated soils being present at the site surface and release of runoff, dusts, gases and vapours.	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)
Operational Phase		
None identified	None identified	None identified
Decommissioning Phase		
Uncontrolled decommissioning and disposal of plant and equipment containing hazardous materials	Release of hazardous materials (including dusts gases and vapours) into the underlying ground	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. 8.4.4 Area 4

The Landfill Gas Facility is to be located on the 'Old Landfill' but there is considerable uncertainty regarding both the contamination levels associated with any buried wastes and the degree of landfill gas generation in this vicinity. The potential land quality effects of the proposed development on the relevant receptors (Section 2.2) identified during this assessment are summarised in Table 22 and the significance of these is assessed in Table 23.

Table 22 Potential geoenvironmental effects identified in relation to Area 4 (Landfill Gas Facility). This area is located on or near the 'Old landfill'.

Activity	Effect	Receptor
Construction Phase		
Disturbance, exposure and spread of existing contamination (particularly buried wastes) in the underlying soils	Exposure (and potential spread) of contaminated soils at the site surface and release of runoff, dusts, gases and vapours	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)
Releases and spillages of polluting materials and wastes during construction	Contamination of the underlying clean soils	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)
Foundation and piling activities	Creation of migration pathways, including for ground gas and vapour migration	• Site staff, construction workers and visitors (human health) • ISWMS infrastructure • (ground and surface water is outside scope)
Construction of building and hardstanding	Impervious footprint has the potential to modify the current gas migration regime, increasing offsite migration.	• Surrounding land users (human health) e.g. residential, commercial/industrial, schools
Operational Phase		
None identified	None identified	None identified
Decommissioning Phase		
Uncontrolled decommissioning and disposal of plant and equipment containing hazardous materials	Release of hazardous materials (including dusts gases and vapours) into the underlying ground	• Site staff, construction workers and visitors (human health) • Surrounding land users (human health) e.g. residential, commercial/industrial, schools • (ground and surface water is outside scope)

8.5 Summary of findings

An assessment of the significance of each of the potential geoenvironmental effects identified with respect to Area 1 is presented in Table 17. In the absence of adequate site investigation data, this identified the following potentially significant effects:

1. Contamination (particularly buried wastes) associated with the OSTSA affecting the health of Site staff, construction workers and visitors;
2. Contamination (particularly buried wastes) associated with the Equipment Storage Area, particularly the OHWSA, affecting the health of Site staff, construction workers and visitors;
3. Failure of the RWL cap (*e.g.* due to flawed engineering, extreme weather events or sea-level rise) leading to the spread of landfill contents over a wide area affecting the health of surrounding land users (e.g. residential, commercial/industrial, schools).

An assessment of the significance of each of the potential geoenvironmental effects identified with respect to Area 2 is presented in Table 20. In the absence of adequate site investigation data, this identified the following potentially significant effects:

1. Contamination (particularly buried wastes) exposed during site development affecting the health of Site staff, construction workers and visitors;
2. Storage and treatment of construction and demolition wastes contaminated with hazardous materials (including asbestos-containing materials) affecting the health of Site staff, construction workers and visitors;
3. Flooding or inundation due to extreme weather events or sea-level rise resulting in the spread of wastes/contamination across a wide area affecting the health of surrounding land users (e.g. residential, commercial/industrial, schools).

An assessment of the significance of each of the potential geoenvironmental effects identified with respect to Area 3 (CUC substation) is presented in Table 21. No potentially significant effects were identified.

An assessment of the significance of each of the potential geoenvironmental effects identified with respect to Area 4 (Landfill Gas Facility) is presented in Table 23. In the absence of adequate site investigation data, this identified the following potentially significant effects:

1. Contamination (particularly buried wastes) exposed during site development affecting the health of Site staff, construction workers and visitors;

9. Mitigation measures:

9.1 Geotechnical

9.1.1 Geotechnical features of the exiting Formations

The poor bearing capacity of the man-made surficial layer and/or of peaty deposits renders it unsuitable support for the proposed development without mitigation. Development loads must therefore be transferred down to the more competent Ironshore or bedrock of the Bluff Formation. Even if these Formations may be considered suitable to support building foundations, they both present some features that may affect their geotechnical competence as mentioned in the following paragraphs.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

9.1.1.1 Ironshore Formation

According to APEC (2021), the Ironshore Formation (*Marl*) is cemented by calcite and can be described as a weak limestone rock in which interbedded layers of cemented and non-cemented material can be found.

The Standard Penetration Test (SPT) performed in this Formation provides generally low blow counts (N values) which does not adequately describe the physical properties of the 'marl'. These low values are often associated with the breaking of the cementation of the 'marl' during the SPT sampling, giving the impression of loose soil.

It is worth noting that the cemented nature of the 'marl' sustains small voids within the Ironshore Formation, in particular at the interface zone with the underlying Bluff Formation. The dimensions of these voids are not mentioned in the available documents. The presence of such voids may affect the stability of shallow footings founded into this Formation.

9.1.1.2 Bluff Formation

Numerous cavities were found in this Formation mainly in the Cayman and Brac Formations. The eventual presence of such cavities at shallow depth beneath the tip of deep foundations (piles) may cause a loss of bearing capacity in case of cavity collapse.

9.1.2 Supplemental geophysical investigation

In order to mitigate the risk that a foundation system (either shallow or deep) interfere with any eventual cavity, supplemental geophysical investigations are recommended. Among the usable techniques, Electrical Resistivity Tomography (ERT), Hydro-Tisar and Refraction seismic Tomography seem the most relevant. They may all allow for the cavity mapping down to a reasonable depth. Using the resulting maps to better define proposed structures limits may help mitigating the risk that a cavity impacts the foundations stability.

These investigation techniques may not be readily available in Cayman and involve mobilization from overseas. The required technical staff and equipment to perform a geophysical investigation is relatively limited (two persons and medium size truck for the equipment).

9.1.3 General geotechnical recommendations

As previously mentioned, both of the existing Ironshore and Bluff Formations may serve as a bearing stratum for the proposed development. Depending on the surficial inappropriate man made deposit thickness in the proposed development footprint, and eventually on the geophysical cavity mapping (see 9.1.2), the use of both shallow and deep foundation systems could be considered. Note that the foundation type to be considered should be designed to resist the seismic forces discussed in Section 3.4 in accordance with applicable building codes.

9.1.3.1 Shallow foundations (column and strip footings)

9.1.3.1.1 Areas with limited man-made deposit thickness

In the areas where the surficial man-made deposit is limited, the man made deposit should first be entirely removed in the whole building footprint down to the Ironshore Formation.

The exposed Ironshore Formation surface should then be carefully inspected, and any cavity/void/crack should be filled using either compacted granular material of concrete.

A geotextile should be spread on the exposed Ironshore Formation (to prevent any loss of the soil particles)

An engineering fill should then be constructed above the geotextile up to the proposed structure foundations and slab levels. The use of geogrids may also be required depending on the subgrade conditions.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

9.1.3.1.2 Areas with higher man-made deposit thickness

In the areas where the Bluff Formation is deeper, ground improvement techniques should be considered to allow for the use of shallow foundation systems. These techniques require generally specific equipment that are not available in the Islands. Among these methods, vibro-compaction, controlled modulus columns (CMCs) and Geopiers seem to be applicable techniques for the proposed development. The choice of the most suitable technique and its design should be done by an experienced ground improvement contractor.

9.1.3.2 Deep foundations (piles)

It is understood that the use of cast-in-place piles is quite common on the island. It should be noted that loss of concrete installed through the vuggy Ironshore Formation and honeycombed Bluff Limestone could be quite significant. Steel casings set in the bedrock can be used to mitigate the loss of concrete but will not mitigate the risk that a cavity be present at shallow depth beneath the pile tip. Geophysical mapping of the cavities may help in mitigating this risk.

In any case, if the use of deep foundations system is considered, the floor slab should imperatively be structural, i.e. supported by foundation elements transferring the loads to the Bluff Formation (by means of piles, micro piles, grade beams etc.).

9.2 Geoenvironmental

9.2.1 Area 1

A number of potentially Significant Effects have been identified with respect to Area 1. In order to mitigate these potential effects, appropriate site investigation activities across Area 1 are needed, which could be combined with any required geotechnical investigation/remediation, to:

– Identify if any waste materials are present and, if so, to determine their characteristics and extent (both lateral and depth);
– Identify any additional sources of contamination; and
– Confirm the concentration of relevant contaminants, particularly in Made Ground, and their extents.

To ensure that any unacceptable risks are adequately managed, including within the Oil and Hazardous Waste Storage Area, where contaminant concentrations exceed the relevant CCTLs the affected materials will be excavated for stockpiling and subsequent removal to the RWL once the RWL is constructed. Materials below the CCTLs do not pose an unacceptable risk and so no mitigation or remediation of such materials is required.

It is essential that the cap used to seal completed sections of the RWL remains intact into the future; this needs to include consideration of foreseeable changes to the local climate and sea level due to climate change. The RWL is intended to be constructed in a phased manner and capping of the first phase is not anticipated until parts of the landfill have reached final tipping levels. Prior to any capping, checks should be made to ensure that the current design is adequate in light of the latest climate data and modelling and procedures put in place to ensure that the ultimate construction is in line with the agreed design.

9.2.2 Area 2

Further potentially Significant Effects have also been identified with respect to Area 2. Mitigation of a number of these also requires additional appropriate site investigation activities across Area 2, which could be combined with any required geotechnical investigation and/or earthworks verification testing, to:

– Identify if any waste materials are present and, if so, to determine their characteristics and extent (both lateral and depth);
– Identify any additional sources of contamination; and

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

– Confirm the concentration of relevant contaminants, particularly in Made Ground, and their extents.

To ensure that any unacceptable risks are adequately managed, where contaminant concentrations exceed the relevant CCTLs the affected materials will be excavated for stockpiling and subsequent removal to the RWL once the RWL is constructed. Materials below the CCTLs do not pose an unacceptable risk and so no mitigation or remediation of such materials is required.

If not already available, a detailed surface runoff management plan should be prepared, which details all areas from which runoff can arise and all locations where surface water contamination may arise. The plan should then propose appropriate and adequate runoff collection and treatment options for the identified runoff. It is recommended that, wherever possible, the principles of Sustainable Urban Drainage Systems (Woods Ballard et al., 2015) should be applied.

9.2.3 Area 3

No potentially Significant Effects were identified with respect to Area 3.

9.2.4 Area 4

A number of potentially Significant Effects have been identified with respect to Area 4. In order to mitigate these potential effects, appropriate site investigation activities across Area 4 are needed, which could be combined with any required geotechnical investigation, to:

– Identify if any waste materials are present and, if so, to determine their characteristics and extent (both lateral and depth);
– Identify any additional sources of contamination; and
– Confirm the concentration of relevant contaminants, particularly in Made Ground, and their extents.

To ensure that any unacceptable risks are adequately managed, where contaminant concentrations exceed the relevant CCTLs the affected materials will be excavated for stockpiling and subsequent removal to the RWL once the RWL is constructed. Materials below the CCTLs do not pose an unacceptable risk and so no mitigation or remediation of such materials is required.

10. Conclusions

10.1 Geotechnical

A review of the Site geology and geotechnical conditions show that the relatively flat Site is located in a high seismic zone and is covered with historical landfill waste material mixed with marl underlain by cemented coral deposits known as Ironshore Formation. These two stratigraphic units are underlain by the Bluff Formation limestone available at a depth of 4 to 6 m below the existing grades. The groundwater table is at approximately 0 m AMSL.

The surficial man-made deposit is considered unsuitable for support foundation loads without mitigation. The use of shallow foundation and conventional slab on grade will require the complete removal of the surficial man-made deposit and the construction of an engineered fill from the Ironshore Formation up the grades. Depending on the exposed Ironshore deposit surface deposit and the information provided by geophysical investigation (if available), geotextile and geogrid may be required to prevent loss of soil particles (geotextiles) and increase the fill rigidity (geogrids).

The Bluff Formation limestone although relatively strong is karstic and is characterized by a honeycombed surface, frequent cavities, and voids. Cast-in-place concrete piles is a preferred foundation option on the island. These can be used for the proposed development. To prevent a loss of concrete in the karstic features, steel casings may be used.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

In order to mitigate the risk that proposed structure foundations interfere with the cavities noted in both the Ironshore and Bluff Formations, a geophysical mapping of these cavities recommended. Using these maps to better define the limits of the proposed structure will help limiting the risk that a foundation footing of a pile tip be affected by a cavity.

The development must be designed for the seismic forces in accordance with the applicable building codes.

10.2 Geoenvironmental

Construction and operation of the ISWMS is expected to result in net environmental benefits in the long-term compared to the unsustainable design and impacts to soil (and groundwater) quality of the current GTLF.

The footprint of the ISWMS can be considered as four areas with differing development histories and future land use profiles:

– Area 1 is within the current GTLF boundary and has a known history of waste treatment and disposal activities, including stockpiling of scrap metal and tires and the storage of waste oils and hazardous wastes. This area has also been subject to the extraction of underlying marl, but the extent of this extraction is unknown.
– Area 2 is outside the boundary of the GTLF. Although it has no recorded development history, limited site investigation activities have indicated the presence of buried wastes of some or all of this Area.
– Area 3 is within the current GTLF boundary but beyond the North Canal and no historical waste activities are believed to have affected this area.
– Area 4 is within the current GTLF boundary and is located in the vicinity of the original 'Old Landfill' or South Mound. The composition of the wastes in this landfill and their gas generation potential are not well characterised.

A thorough review of all the available information did not identify any significant site investigation data (for example buried waste locations, contaminant concentrations or ground gas monitoring) that would form the basis for establishing current baseline conditions (geoenvironmental) and allow a quantitative assessment of any land quality risks. Such site investigation data is needed prior to construction of the Project.

However, the available information did allow a qualitative assessment of the potential land quantity risks. Based on the current proposed design (Chapter 4), a variety of potential environmental affects associated with the construction, operation and decommissioning of the ISWMS has been identified. A number of these affects have been assessed as potentially Significant Impacts

Appropriate mitigation measures for these potentially Significant Impacts have been recommended, many of which are predicated on the collection of suitable and sufficient site investigation data to allow the current levels and extent of any contamination to be ascertained and the ground gas regime characterised, or the pre-emptive excavation of materials that exceed the relevant CCTLs to the RWL. Given the nature of the ISWMS development, it is likely that any pre-existing wastes present will not result in unacceptable levels of contamination. Finally, procedures should be established to ensure that imported fill materials do not contain sufficient hazardous materials, which pose risk to construction workers.

GRAND CAYMAN PROPOSED INTEGRATED SOLID WASTE MANAGEMENT SYSTEM GEOTECHNICAL INVESTIGATION AND REPORT

1.0 INTRODUCTION

APEC Consulting Engineers Ltd (APEC) carried out a geotechnical investigation at the site of the proposed Grand Cayman integrated solid waste management system (ISWMS) on parcel 13D431. The site is located in the George Town industrial park area.

The site is bounded to the north and east by the George Town Landfill (GTLF) and to the south by industrial land uses. To the west, the site is bounded by undeveloped land and the Esterley Tibbetts highway (ETH) further west. The site grade elevation varies from approximately 2 to 12 feet above mean sea level (MSL).

The site location and proposed ISWMS facility are shown in **Figures 1** and **2**. The conceptual design for the proposed ERF building is shown in **Figure 3**. As the ERF is considered a power-generating station and public utility facility, it is understood that the ERF building will be assigned as a Risk Category III facility (IBC 2009 and ASCE 7). The geotechnical investigation fieldwork was carried between November and December, 2020.

The report will be required as part of the submission documents for the Cayman Islands Planning Department's Special Inspector program.

Figure 1 - Site location plan

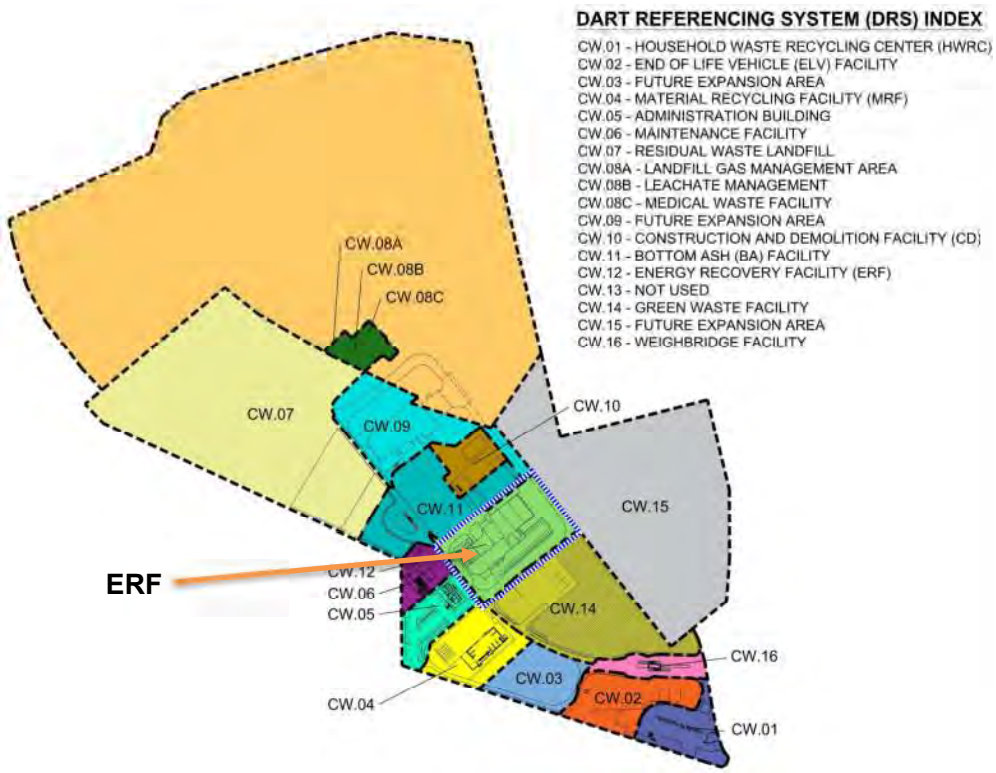

Figure 2 - Proposed ISWMS Facility Layout

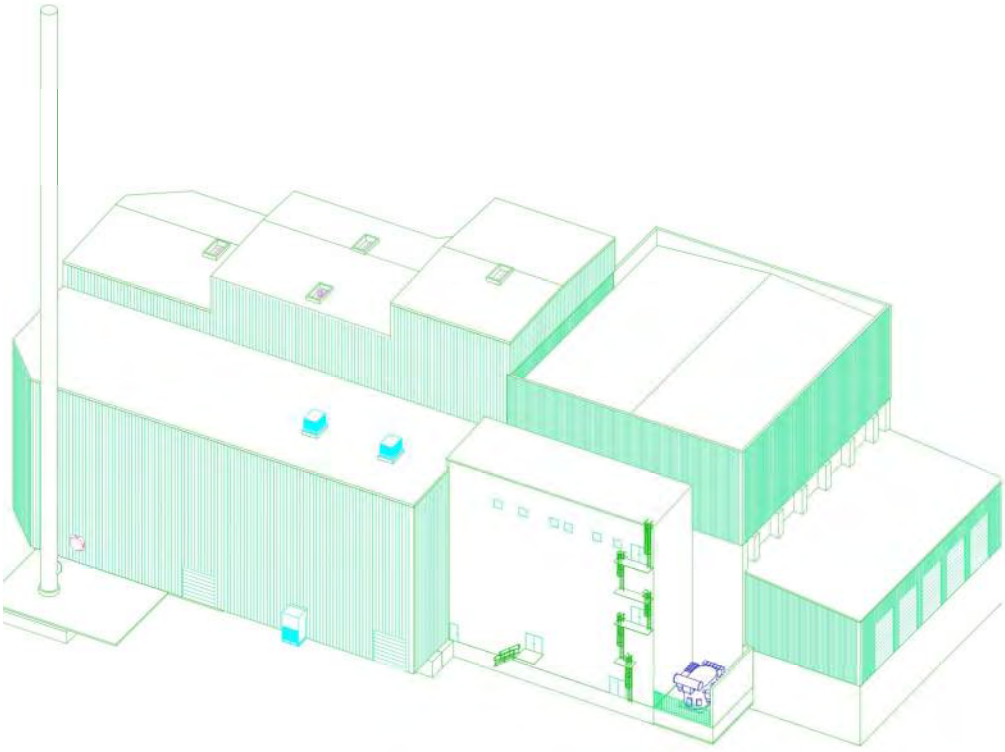

Figure 3 - Proposed Energy Recovery Facility

2.0 SCOPE & LIMITATIONS OF REPORT

This report comprises a description of the field investigation carried out under APEC's supervision; a geotechnical engineering appraisal of the sub-surface soil conditions and recommendations for suitable foundation system(s) and corresponding foundation design parameters. The recommendations and conclusions contained in this report are based on the results of subsoil investigations made at specific locations. These results are extrapolated to give an overall impression of the prevailing soils condition. Local deviation from the conditions predicted in this report may occur. The nature or extent of variations throughout the subsurface profile may not become evident until the time of construction. If variations become evident, it may be necessary to re-evaluate the recommendations provided in this report.

This report is intended for use by the client or his agents for the foundation design of proposed structure(s) as herein described on the site mentioned in this report. This report may not be relied upon by a third party for any purpose without the written consent of this practice. No liability is assumed to any third party using this report for whatever reason.

This report has been prepared in accordance with generally accepted local geotechnical engineering practices; no other warranty is expressed or implied.

APEC retains full copyright rights of all its designs, drawings, specifications, reports and other documentation. Our copyright is not released to the client at any time. Copyrighted material includes all our engineering analysis, designs, reports, drawings, specifications or any other form of conveying professional advice and services.

3.0 CAYMAN GEOLOGICAL SETTING

The Cayman Islands are located on the Cayman Ridge. This ridge forms the southern boundary of the North American plate and the northern boundary of the Cayman Islands Trough. Their position near the Oriente Transformation Fault and the Mid-Cayman Rise means that they are located in a tectonically active area. Carbonate rocks exposed on the islands record successive deposition - erosion cycles that have occurred over the last 30 million years. Sea level was the critical factor that controlled deposition because highstands led to deposition whereas lowstands led to the weathering of the previously deposited carbonates.

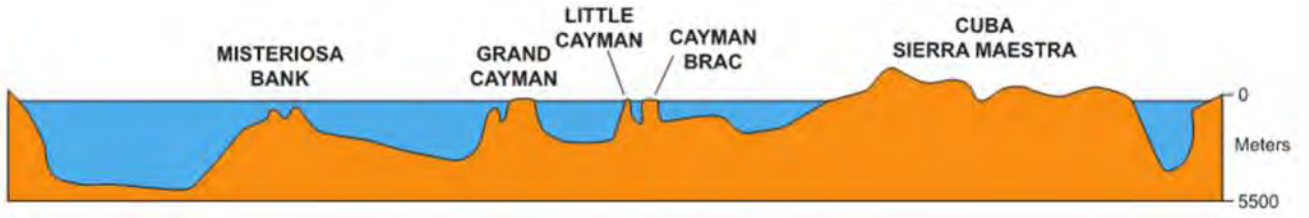

Figure 4 - Cross section along Cayman Ridge (Jones, 2012)

The three Cayman Islands are the tops of pinnacles reaching up from the depths of the ocean as shown in **Figure 4**. Each island appears to be based on a granodiorite foundation succeeded by a cap of basalt and then tertiary carbonates (limestones, dolomites, dolomitic limestones). The thickness of the carbonate cap exceeds 1,300 feet. The actual thickness is not known.

Dr Brian Jones and others have developed a nomenclature for the Cayman Islands stratigraphy. The central part of each island is formed of massive tertiary carbonates called the Bluff Limestone. This Bluff Formation grouping includes the Brac, Cayman and Pedro Castle Formations. The Bluff Formation is a series of medium to fine grained chalky limestone which has re-crystallized in many areas to form a hard white limestones and dolostones. The stratigraphy described is shown diagrammatically in **Figure 5**.

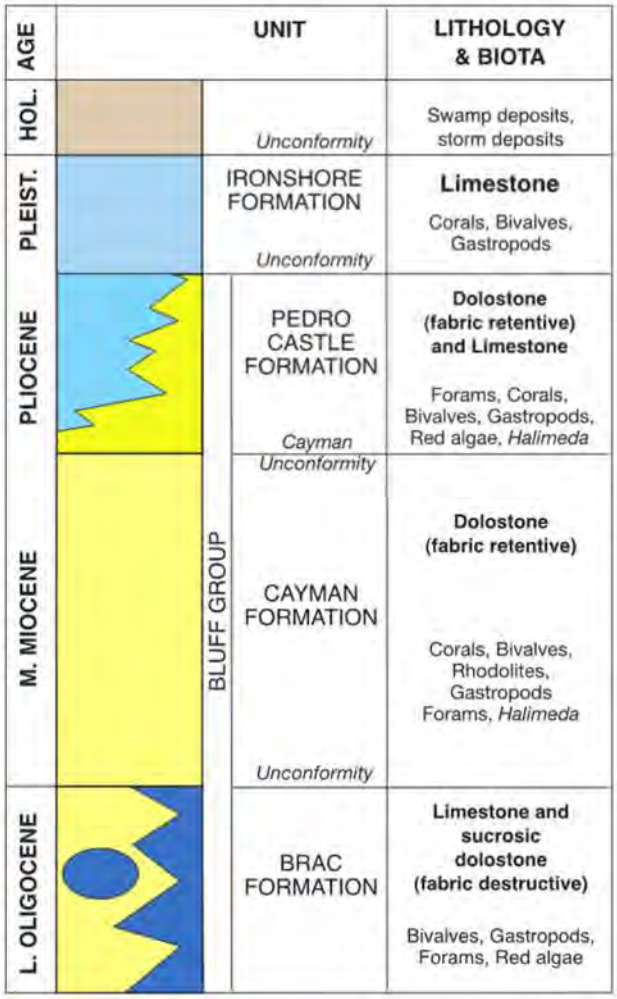

Figure 5 - Stratigraphy of the Cayman Islands (Jones 2012)

The surface of the Bluff Formation is typically jagged because of the development of an extensive karst system. Honeycombed rock pinnacles, fissures and sinkholes are common surface landforms, whereas caves occur in the subsurface. Cavities and caves are filled or partly filled with calcite cement, terra rossa, terrestrial oncoids and freshwater limestone. The Bluff Formation is surrounded and partly onlapped by the Late Pleistocene Ironshore Formation. This Ironshore Formation consists of unconsolidated coralline limestone which is often degraded and decomposed to form a soil type known locally as 'marl'.

The name of the Ironshore Formation was derived from the local Caymanian term for the low, case-hardened rocks that commonly occur around the shorelines of the Islands. The term 'Ironshore' refers to the hard calcrete crust that is typically formed on the weathered surface of the rocks in this formation. The Ironshore Formation is typically formed of friable, poorly consolidated reef limestones, calcarenites and oolitic limestone that are cemented by calcite.

The Ironshore Formation ranges from subtidal lagoonal facies at its base, through lower shoreface facies, to upper shoreface, to foreshore-backshore facies. Most limestones in the Ironshore Formation were deposited in a large lagoon. The Bluff and Ironshore Formations are separated from each other by disconformities. These represent weathering surfaces that developed during the periods of subaerial exposure that followed each phase of deposition. The carbonate rocks of the Cayman Islands contain numerous vugs and moulds caused by the dissolution of the coral fauna skeletons. Tree roots commonly penetrate through the rock to the water table. The roots have formed pathways which have filled with organic debris over time.

The Cayman and Pedro Castle Formations are extensively jointed due to repeated periods of karst development over the last 30 million years. The joints are generally vertical in orientation and run parallel to adjacent shorelines. The joints are often solution widened. At many localities the joints are filled or partly filled with a variety of rock types.

As can be seen in **Figure 6**, the Ironshore Formation is typically present as the uppermost strata in the western part of the island where the proposed ISWMF site is located.

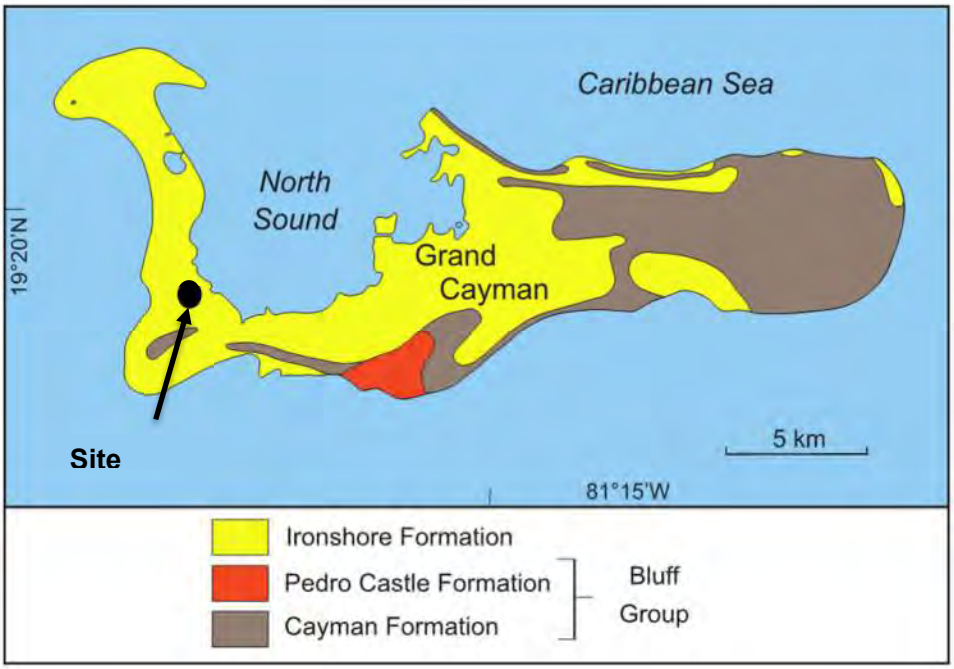

Figure 6 - Geological map of Grand Cayman (Jones 2012)

The Ironshore Formation is overlain by peat deposits which have been laid down over the last 2,000 years. The peat is subjected to seasonal flooding and is waterlogged for much of the year.

4.0 REVIEW OF AVAILABLE SEISMICITY INFORMATION

4.1 TECTONIC SETTING & SEISMICITY

Grand Cayman is in a tectonically active area. Dr. Jones (2012) describes in detail the tectonic setting and seismicity of Grand Cayman in relation to the fault lines which run to the south of the island (**Figure 7**).

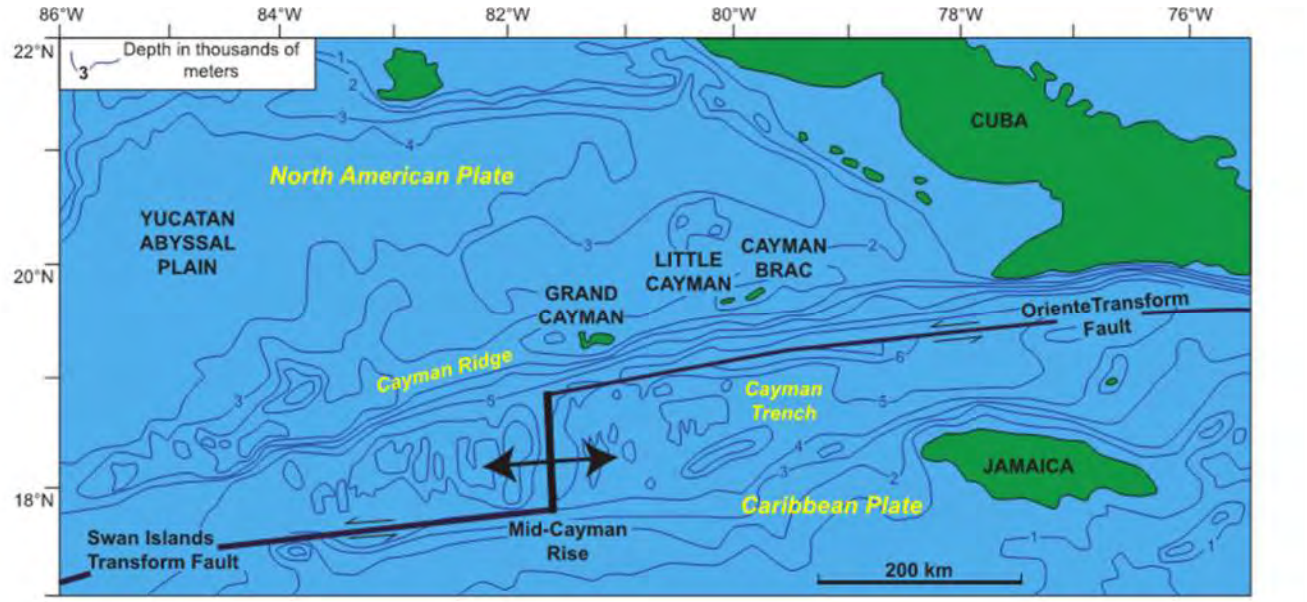

Figure 7 - Caymans Islands fault locations (Jones 2012)

There are few detailed records of the earthquakes that have affected Grand Cayman prior to 1990. Since 1990, there have been six earthquakes with a magnitude greater than 5.5 with the highest being 6.8 on December 14, 2004, and the latest on January 28, 2020 (6.1) as highlighted in **Figure 8**.

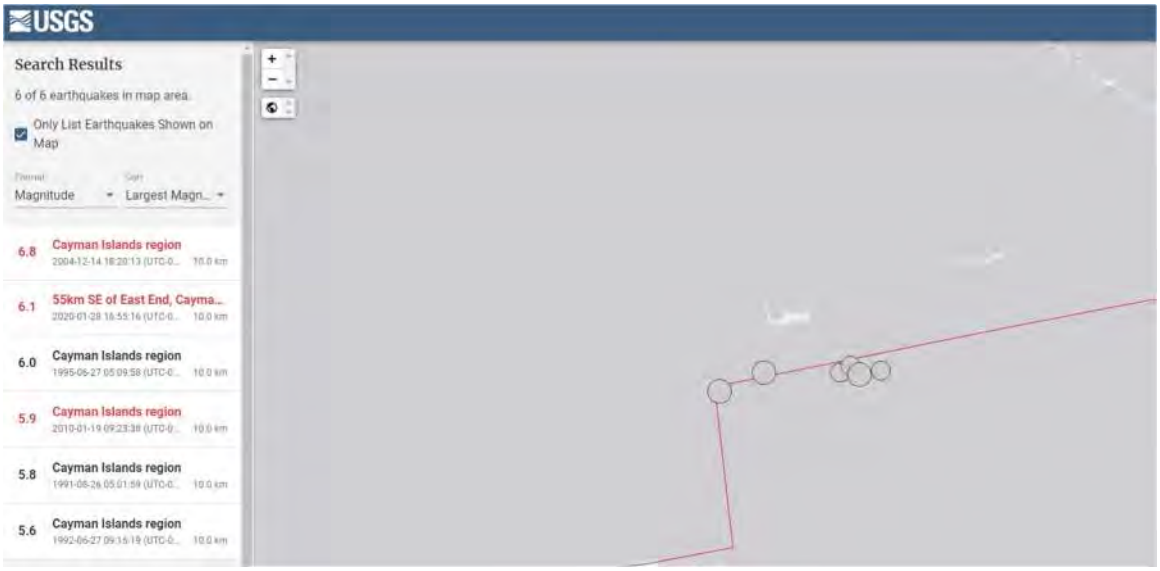

Figure 8 - Cayman Islands Fault Locations (United States Geological Survey)

4.2 SEISMIC GROUND MOTION VALUES

The seismic design for structures in the Cayman Islands is in accordance with the 2009 International Building Code (IBC) as modified by the Cayman Islands Building Control Unit (BCU) through the Cayman Islands Building Code. The IBC references the American Society of Civil Engineers (ASCE) standard ASCE 7: "Minimum Design Loads for Buildings and Other Structures" as an acceptable design standard. Site specific seismic studies, as defined in ASCE 7-05, carried out for Camana Bay, George Town, Grand Cayman (immediately north of the subject site) provided the following design parameters.

S_S	**0.659g**
S_1	**0.300g**

where:

MCE = Maximum Considered Earthquake,

2475 year return period (2% chance of exceedance in 50 years) on Class C site

S_S = MCE, 5 percent damped, spectral response acceleration parameter at short periods

S_1 = MCE, 5 percent damped, spectral response acceleration parameter at a period of one second

The ERF structures and components must be designed in accordance with these parameters, refer to **Section 9.0** for further geotechnical discussion and design parameters.

5.0 HURRICANE IMPACT CONSIDERATIONS

Grand Cayman is located in the tropics and is prone to tropical cyclone activity. The predominant features of a tropical storm/hurricane event are rainfall, wind, wind-borne debris, wave action and seawater flooding due to storm surge and wave run-up. The facility design parameters in relation to such events will include design as well as operational measures to mitigate the impacts of such events. The design parameters associated with environmental conditions due to potential flooding and wave impact of the site are summarised below.

5.1 SEAWATER FLOODING AND WAVE IMPACTS

Based on data gained during Hurricane Ivan, a 1 in 100-year return period still water elevation at the site of 8ft MSL or higher was determined. The Cayman Island Lands and Survey flood mapping at the site for Hurricane Ivan is reproduced in **Figure 9** for conversational information purposes only**.**

Using US Federal Emergency Management Agency (FEMA) guidance, a base flood elevation (BFE) of 9ft MSL is recommended for all buildings and structures on this site. A design flood elevation (DFE) of 11ft MSL is recommended for all ISWMF buildings assigned as Risk Category III or IV (essential facilities) per ASCE 7 – this includes the ERF building. Refer to the *Design Flood Elevation Review* prepared by this office in August 2020, included in **Appendix A**.

BFE	**9ft MSL**
ERF (Critical) DFE	**11ft MSL**

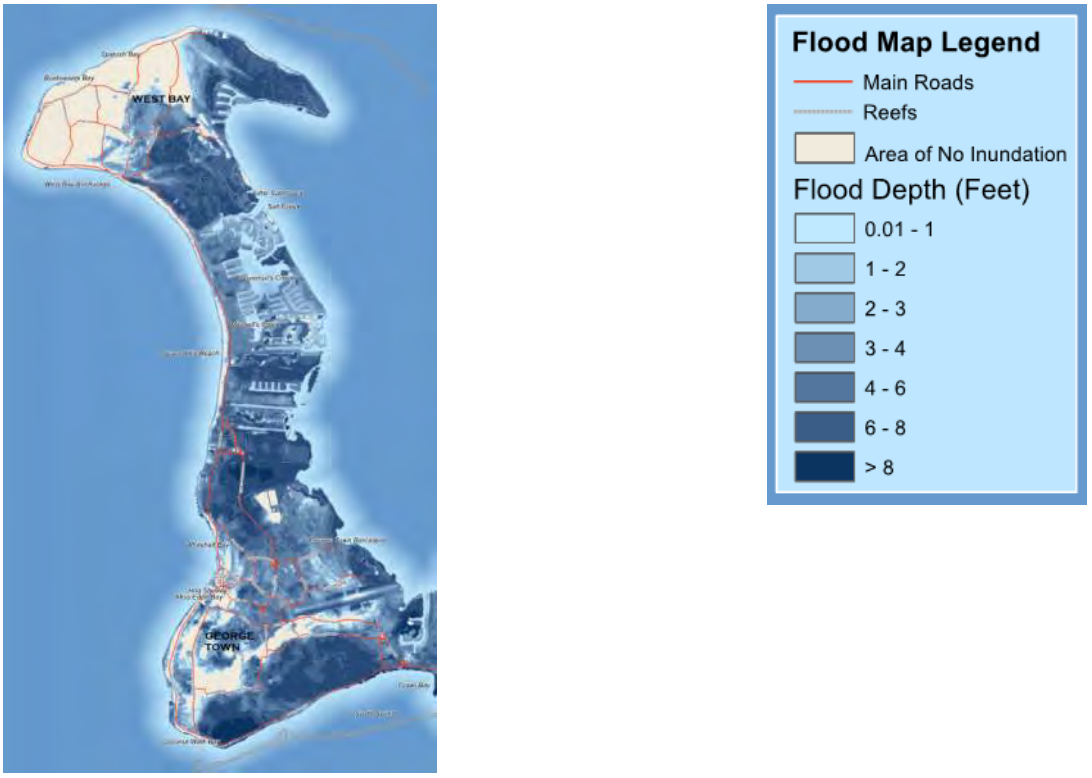

Figure 9 – Hurricane Ivan Flood Map for West Bay Peninsula (Lands & Survey Department)

The Cayman Islands Planning Department requires that the lowest (non-protected basement) habitable floor level for this area of Grand Cayman should be at least FIVE feet (5ft) above MSL, i.e. two feet (2ft) above the Vidal Bench Mark. It is important to note that the Department does NOT require the habitable floor levels to be placed at the higher elevations recommended in this report.

The United States Federal Emergency Management Agency (FEMA) Coastal Construction Manual was used to estimate the base flood elevation (BFE) during a coastal flooding event. The BFE represents the lowest possible floor elevation (subject to upward adjustment by other design criteria) but can also be used to estimate the requirements for other protection structures.

The site for the proposed ERF building is classified as within FEMA's Coastal A-Zone (**Figure 10**). Structures within the Coastal A-Zone are at risk of surge and waterborne debris impact, scour and erosion in the event of major storms. The majority of Grand Cayman falls within either category V or A due to the typically low ground elevations. The BFE is the sum of the 100-year still water elevation plus wave effects.

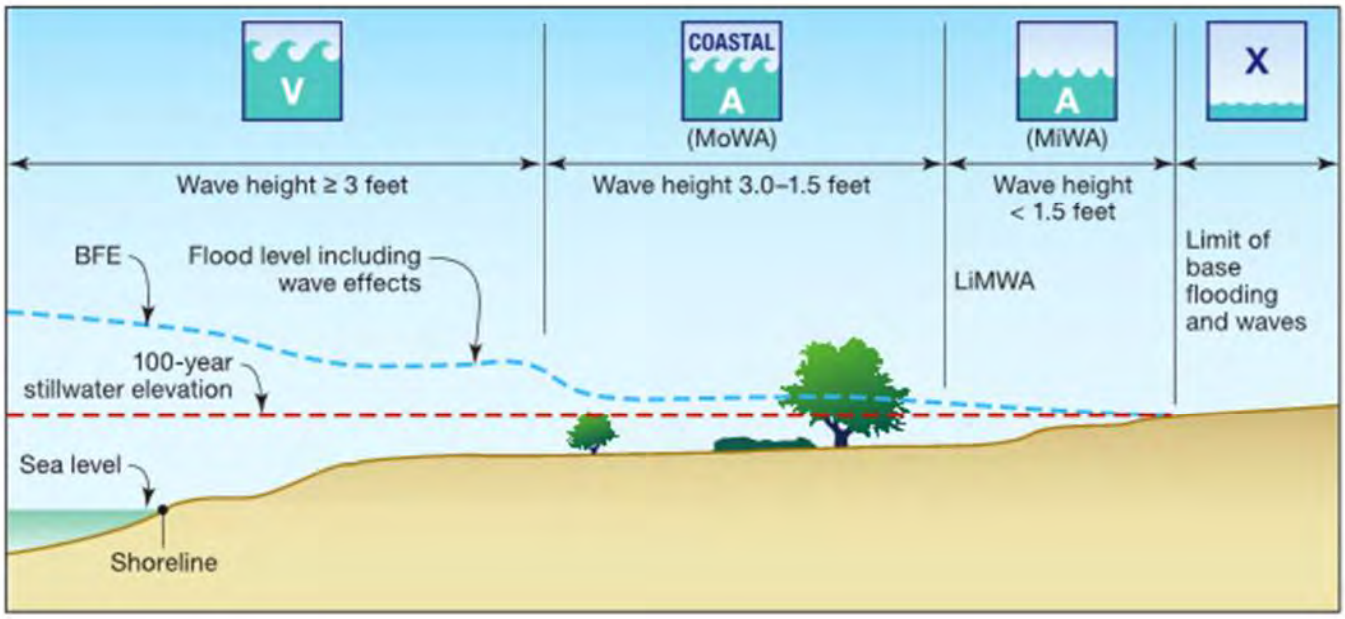

Figure 10 – Typical Shoreline and Associated Flood Zones (FEMA)

The incorporation of flood barriers in the building design should be considered to provide enhanced resistance to flooding. It is also recommended that buildings be designed to resist the buoyancy forces associated with flooding up to the BFE should the lower floors be dry proofed (protected against flood water ingress to the building interior).

The seawater flooding elevations discussed in this section do not account for any potential sea level rise predictions (see **Section 6.3**).

6.0 CLIMATE CHANGE IMPACTS

The following is taken from a study carried out by APEC for the ETH Cayman Parkway, in June 2016. Climate change[1] incorporates changes in temperature, rainfall, tropical cyclones, earthquakes and sea levels. The impact of climate change predictions may have an effect, not only on the physical components and operation of the proposed facility, but also on the ecological and socio-economic environments in the vicinity of the site.

Several publications on the predicted impacts of climate change were previously reviewed. The publications cover a mix of geographical areas from specific Caribbean wide research to the global effects of climate change.

The following sections itemize the predictions contained in the publications on the possible effect of climate change on rainfall, tropical cyclones / hurricanes, and sea level rise. Most of the publications reviewed refer to 2100 as the design horizon year.

6.1 RAINFALL

A summary of the predictions taken from the publications on the effect of climate change on rainfall levels is provided in **Table 1**.

Publication Author	Horizon Year	Commentary
Cayman Islands National Climate Change Committee	2100	• Changes in rainfall patterns expected with generally heavier rainfall events • Significantly less rainfall region wide • Conditions predicted to become more El Niño-like, i.e. drier Caribbean region
Intergovernmental Panel on Climate Change (IPCC)	Not Given	• Significant future increase in heavy rainfall events • Mean rainfall is projected to decrease • Increases in the frequency and severity of floods and droughts are projected to adversely affect sustainable development • In coastal areas, sea level rise will exacerbate water resource constraints due to increased salinization of groundwater supplies
US National Research Council	Not Given	• A higher fraction of rainfall is expected to fall in the form of heavy precipitation events as temperatures increase
US Global Change Research Program	Not Given	• Projections of future changes in precipitation show overall increases in the global average, but with substantial shifts in where and how precipitation falls • The widespread trend toward more heavy downpours is expected to continue, with precipitation becoming less frequent but more intense

Table 1: Summary of Reviewed Publications into Future Rainfall Predictions

[1] Climate Change is defined as a statistically significant variation in the mean state of the climate or its variability, persisting for an extended period (typically decades or longer). Climate change may be caused by natural internal processes or external forcings or by persistent anthropogenic changes in the composition of the atmosphere or land use.

Although there is no quantitative estimate of the effect of climate change on rainfall / precipitation, all publications agree that there will be an overall decrease in rainfall but with shifts in the rainfall intensity and rainfall pattern.

6.2 Tropical Cyclones / Hurricanes

A summary of the predictions taken from the publications into the effect of climate change on tropical cyclones / hurricanes is provided in **Table 2**.

Publication Author	Horizon Year	Commentary
Cayman Islands National Climate Change Committee	Not Given	• Stronger hurricanes expected • Substantially more rainfall during the storm and peak winds intensity
Intergovernmental Panel on Climate Change (IPCC)	Not Given	• Future hurricanes will become more intense • Larger peak wind speeds and more heavy precipitation
US Global Change Research Program	Not Given	• Ocean temperatures lead to stronger storms with higher wind speeds and more rainfall • Changes in wind speed and direction with height are also projected to increase in some regions, and this tends to work against storm formation and growth
US National Research Council	Not Given	• Growing certainty that climate change could lead to increases in the strength of hurricanes

Table 2: Summary of Reviewed Publications into Future Hurricane Predictions

There is a mixture of predictions in the publications with some publications predicting stronger, more intense hurricanes and other publications saying that there is still uncertainty on the effect of climate change on tropical cyclones / hurricanes.

6.3 Sea Level Rise

Most of the reviewed publications on sea level change utilize models to estimate the rise in sea levels over the rest of this century, with the majority of the publications using 2100 as the horizon year. A summary of the predictions taken from the publications has been provided in **Table 3**.

As all the publications state, estimating sea level rise (SLR) due to changing climatic conditions is based on several assumptions and models and the accuracy of results cannot be guaranteed. An estimate has been made of the predicted sea level rise due to climate change. For the purposes of this review, we have simply taken the mean value of all predictions relating to the Caribbean and South East Florida for the 2100 horizon year only (shaded rows). The mean value for predicted sea level rise for the year 2100 is 2.0 ft (this is supported by Dr S. Douglass, South Coast Engineers).

A recent review of engineering studies suggests a lower value for SLR of 1.2 feet with an upper value of 3 feet by 2100, with a mean of 2.0 feet.

Publication Author	Horizon Year	Max / Min / Mean	Predicted Sea Level Rise (feet)
Cayman Islands National Weather Service assisted by Caribbean Community Climate Change Centre and the Cuban Institute of Meteorology (2011)	2100	Min Max	0.40 2.60
Cayman Islands National Climate Assessment (Appendix 2) (2011)	2100	Min Max	0.40 2.60
Environment & Coastal Zone Management Special Issue Committee (2002)	2100	Mean	1.00
Intergovernmental Panel on Climate Change (IPCC) (2007)	2100	Max	1.90
Mainstreaming Adaptation to Climate Change (2005)	2080	Mean	1.20
Pew Center on Global Climate Change (2009)	2100	Min Max	6.50 9.80
Southeast Florida Regional Climate Change Compact (Table 4) (2011)	2100	Min Mean Max	1.96 3.34 4.71
Southeast Florida Regional Climate Change Compact (Table 5) (2011)	2100	Mean	2.50
Southeast Florida Regional Climate Change Compact (Table 5) (2011)	2110	Mean	2.83
The Center for Science and Public Policy	2100	Mean	1.25

US Global Change Research Program	2100	Min Max	0.67 2.00
US National Research Council	2100	Min Max	1.80 6.60
NOAA Technical Report NOS CO-OPS 083	2060	Mean	2.00

Table 3: Summary of Reviewed Publications into Sea Level Rise

6.4 SUMMARY OF REVIEWED PUBLICATIONS ON CLIMATE CHANGE IMPACTS

The reviewed publications predict the potential impact of climate change on rainfall, tropical cyclones / hurricanes and sea levels. The prediction of climate changes is not an exact science and is based on theoretical models. The preceding sections have itemized these predictions from the internationally based research. Where applicable, an arithmetic mean has been taken of these predictions in order to quantify the potential impact. **Table 4** provides a summary of these values.

Climatic Condition	Prediction (Calculated Mean)	Horizon Year
Rainfall	• Heavier rainfall events • Significantly less rainfall	Not Given
Hurricanes	• Stronger, more intense hurricanes expected	Not Given
Sea Levels	• 2.0 feet increase	2100

Table 4: Summary of Predicted Climate Change Impacts Review

7.0 SUMMARY OF FIELD INVESTIGATIONS AT THE PROPOSED SITE

Fieldwork for the geotechnical investigation was carried out in two stages between November and December 2020.

A total of twenty-six (26) trial pits were undertaken on the subject site, three (3) of which were within the footprint of the proposed ERF building. The pits were advanced by mechanical excavator as part of the first stage of works (see **Figure 11**).

As part of the second stage, a local drilling contractor was retained to undertake the drilling of the boreholes, which were advanced using a truck-mounted rotary drill employing rotary air flush drilling techniques with diamond plug bits. Fifteen (15) boreholes were advanced to a maximum depth of 24.5 feet below ground level (BGL) (see **Figure 11**), Six (6) of which were advanced within the ERF footprint. Standard penetration tests (SPTs) were carried out in each borehole. The work was undertaken under the field supervision of an APEC engineer.

Ten-foot cores were advanced and retrieved from the rock encountered in all boreholes. The rock cores were delivered to APEC's office in George Town, where they will be stored for a period of three months and will then be discarded.

The trial pit & borehole logs and location plan are included in **Appendix B.**

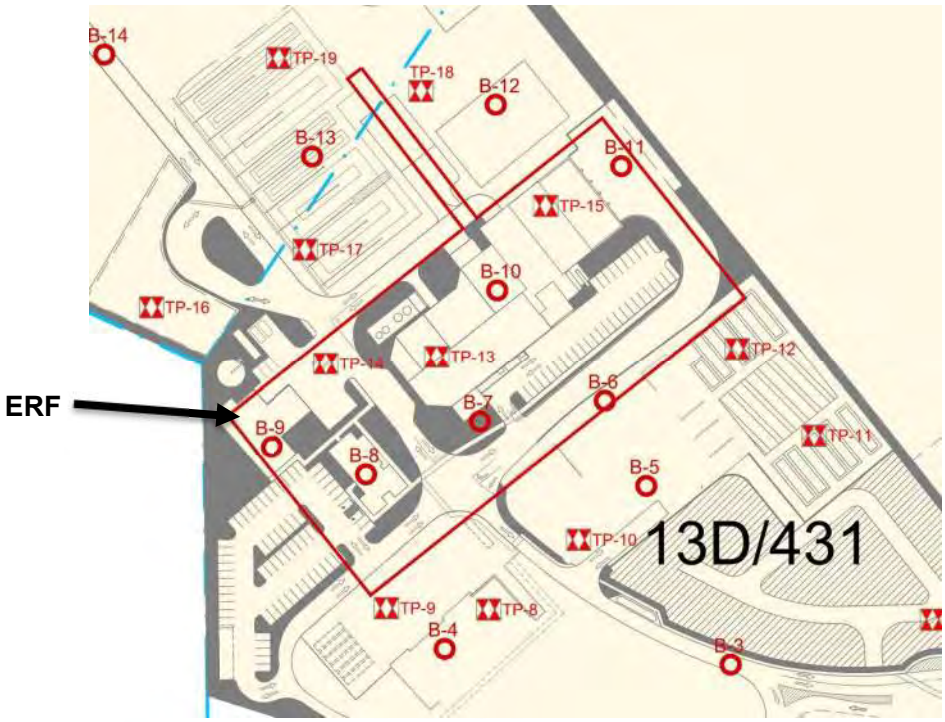

Figure 11 – Approximate Locations of Trial Pits & Boreholes

8.0 SOIL CONDITIONS

8.1 GEOLOGY

There are distinct subsurface conditions present on the site. Due to the historic use of this site, there is municipal waste material present in the vast majority of trial pits. This waste was found to be mixed with 'marl' and topsoil, possibly due to the addition of daily cover during waste landfilling works. **Table 5** provides a summary of the near surface soil profiles generally encountered.

Strata	Approx. thickness/ elevation
Topsoil 'Marl' fill and municipal waste mix	Surface elevation varies from 4 to 12ft MSL Thickness 6 to 16ft
Highly compressible organic material ('peat')	Thickness 0 to 2ft
'Marl' (Ironshore Formation)	Thickness 6 to 12ft
Dolostone rock (Pedro Castle Formation)	Top of rock varies from 15 to 24.5 ft BGL
Ground water	Ground water level varies average of 2ft MSL*

*average levels measured within monitoring wells, variation tidally influenced

Table 5 – Typical soil profile summary

The following describes the material referenced in **Table 5**.

Topsoil 'Marl' fill and municipal waste mix

The mix of topsoil, marl and municipal waste is believed to have been deposited over thirty years ago. Aerial imagery indicates the area was used as a landfill sometime between the 1970s and 1980s. The 1994 aerial photography shows the site as being covered. This is consistent with an environmental assessment report prepared in 1991 by Post, Buckley, Schuh and Jernigan Inc. (PBSJ) which refers to landfilled waste on an adjacent property not owned by CI Government. At the time it was proposed that CIG purchase the property and expand the new landfill over the old landfill.

Organic Peat

One out of three trial pits and one out of six boreholes within the ERF contained a 2 ft to 5 ft thick layer of highly compressible organic material (peat) at depths of between -2 ft and +2 ft MSL. Deeper pockets ('moleholes') of peat may be present on the site which may not be detected, if at all, until construction commences.

Ironshore Formation - 'marl'

Native limestone 'marl' (Ironshore Formation) was encountered in all test locations. Based on the SPT blow counts, the 'marl' would generally be characterized as loose to compact. In our opinion the general use of the SPT blow counts to correlate the engineering properties of the 'marl' does not generally provide a true characterization of the material. 'Marl' typically exhibits greater engineering characteristics than blow counts would ordinarily indicate. See **Section 9.0** for discussion of the properties of the 'marl'.

As identified and classified by Dr Jones, patch reefs occur within the Ironshore Formation in the West Bay peninsula. The patch reefs occur at the bottom of the formation with lagoonal and oolitic limestones in the upper horizons. These reefs were created and aerially exposed more than 125,000 years ago and subsequently covered by the deposition of lagoonal limestones as sea level rose. Patch reefs are surrounded by lagoonal sands and muds. These former reefs contain hard cemented layers and rubble from the coral reefs, including boulders and cobble sized material. As an indication of the density of the cemented reefs, driven steel piles have achieved an acceptable 'set' when the shaft is obstructed by a patch reef. Cavities will be encountered in the patch reef zone given the manner in which these reefs are created.

Cavities are also typically found in the epikarst[2] zone which is common throughout the island at or near the interface between the limestone 'marl' (Ironshore Formation) and rock (Pedro Castle and Cayman Formations).

Limestone/Dolostone rock

The upper horizon of limestone rock (Pedro Castle Formation) was encountered between 15.0 and 24.5 feet BGL. Core samples of the rock were taken in all boreholes. Core recovery was variable across the boreholes sampled from 50% in BH-6 to 96% in BH-7 with Rock Quality Designation (RQD) ranging from 27% to 79%.

Laboratory testing was not possible due to the laboratory refusing to test material containing municipal waste.

8.2 GROUND WATER

The stabilized ground water elevation on the site during Mean High Water Spring (MHWS) tide is estimated to be approximately 2.0 ft above MSL. This correlates with the typical ground water elevations of between 1.5 and 2.5 ft above MSL experienced on Grand Cayman that depend on site location, rainfall and atmospheric conditions, tides etc. The Highest Astronomic Tide (HAT) reported to 2018 for Grand Cayman is 2.62 ft MSL. These elevations do not account for tropical cyclone induced ground water level fluctuations.

The groundwater ingress into the trial pits was noted as being slow.

[2] The zone of weathering found at the upper surface of the 'limestone bedrock'. Weathering, stress release and dissolution of the limestone surface results in an irregular surface and limestone pinnacles and boulders are common within the zone.

9.0 GEOTECHNICAL DISCUSSION

9.1 THE IRONSHORE FORMATION

The Ironshore Formation (commonly known as 'marl') is cemented by calcite and can be described as a weak limestone rock. Interbedded layers of cemented and non-cemented material can be found.

Island constraints limit the range of available geotechnical investigation techniques. The commonly used Standard Penetration Test (SPT) does not adequately describe the physical properties of the 'marl'. Where they occur, low blow counts (N values) are often associated with the breaking of the cementation of the 'marl' during the SPT sampling, giving the impression of loose soil. This conclusion has been validated by the performance of as-built structures bearing on the native 'marl' as well as by in-situ seismic downhole, crosshole and resistivity testing and laboratory testing carried out for previous projects on Grand Cayman. The cemented nature of the 'marl' sustains small voids within the layer. These investigation techniques are not readily available in Cayman and involve mobilization of special equipment and crew from overseas.

More recently, another form of seismic exploration known as Multichannel Analysis of Surface Waves (MASW) has been used in Grand Cayman to verify the physical properties of the marl material. MASW evaluates ground stiffness by measuring shear-wave velocity (Vs) of subsurface in 1-D, 2-D, and 3-D in the most common depth range of 0 - 100 feet. The results from the MASW testing gave similar velocities to those determined from seismic testing using boreholes on previous projects in the vicinity of this site.

9.2 THE EPIKARST ZONE

Evidence of the epikarst zone (or the "inconformity" as defined by Dr Jones) was detected while advancing all of the boreholes. The epikarst zone can be found throughout the island. As previously described, the joints in this zone are typically filled with calcite cement, terra rossa, reef rock terrestrial oncoids and freshwater limestone. The epikarst zone typically occurs at the interface of the 'marl' and carbonate rock layers. This stratum also contained several cavities as indicated by the low core recovery in some of the boreholes and noted during the SPTs.

9.3 SITE COEFFICIENTS AND MODIFIED SPECTRAL ACCELERATION PARAMETERS

The site is classified as Class C (soft rock) under ASCE 7-05. The corresponding site coefficients are as follows.

F_a = short-period site coefficient = 1.136 ..... (ASCE 7 Table 11.4-1)
F_v = long-term site coefficient = 1.5 ..... (ASCE 7 Table 11.4-2)
$S_{MS} = F_a S_s$ = 1.136 x 0.659 = 0.749 g ..... (ASCE equation 11.4-1)
$S_{M1} = F_v S_1$ = 1.5 x 0.300 = 0.450g ..... (ASCE equation 11.4-2)
where
S_{MS} = the MCE, 5 percent damped, spectral response acceleration at short periods adjusted for site class effects
S_{M1}= the MCE, 5 percent damped, spectral response acceleration at a period of one second adjusted for site class effects

9.4 Design Spectral Acceleration Parameters

The design spectral acceleration parameters for this site are as follows.

$S_{DS} = 2/3\ S_{MS} = 0.499g$ (ASCE equation 11.4-3)

$S_{D1} = 2/3\ S_{M1} = 0.3g$ (ASCE equation 11.4-4)

where

S_{DS} = design, 5 percent damped, spectral response acceleration parameter at short periods

S_{D1} = design, 5 percent damped, spectral response acceleration parameter at a period of one second

Based on the risk category and soil classification, it is understood that the ERF building will need to be designed as a Seismic Design Category (SDC) D structure. Other buildings within the ISWMS facility are likely to be designated SDC C structures.

9.5 Geologic Site Hazards Review

9.5.1 Liquefaction and Differential Settlement

There is no potential for liquefaction at most of the site due to the competent nature of the underlying marl and bedrock and their relative shallow elevation.

9.5.2 Slope Failure

There is no potential for slope failure within the soil and rock strata at the ISWMS site.

9.5.3 Surface Fault Rupture

Surface fault rupture and surface displacements are not anticipated. See **Section 4.0**.

10.0 FOUNDATION DISCUSSION

Two options for a suitable foundation system under the Energy Recovery Facility (ERF) building are considered as follows. We have limited our review and recommendations to solutions that have been successfully employed in Grand Cayman. The range of feasible ground improvement and deep foundation systems for projects in Cayman is limited by available equipment on island and the challenges of transporting specialist plant, equipment and specialist personnel.

Option 1: Ground improvement for a reinforced concrete shallow foundation system.

Option 2: The installation of reinforced concrete continuous flight auger (CFA) piles supporting reinforced concrete substructure & grade beams.

10.1 OPTION 1: GROUND IMPROVEMENT TECHNIQUES FOR SHALLOW FOUNDATIONS

Vibro compaction techniques are suggested as part of a ground improvement works strategy for this project to create an acceptable ground bearing formation for the building foundations and to meet the industry established settlement limits for acceptable building foundation performance.

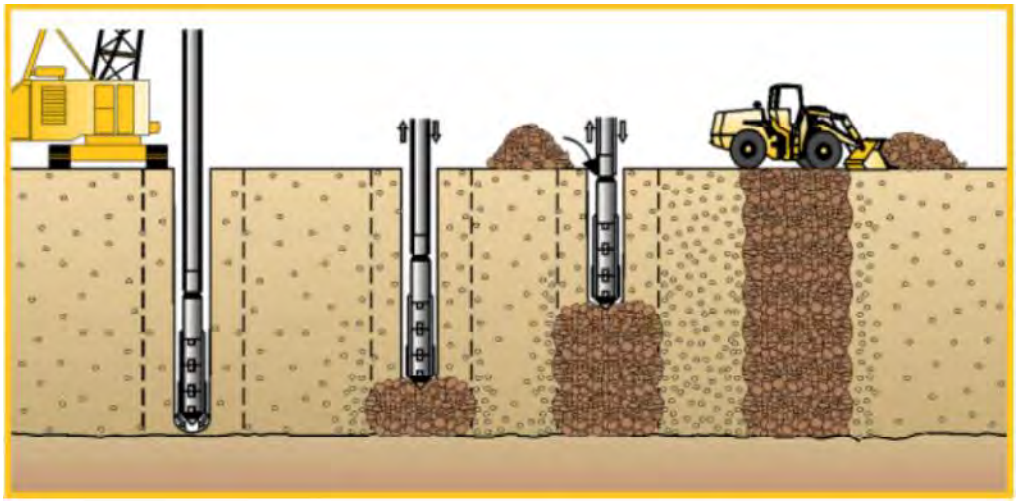

Figure 12 – Vibro Compaction

To create an adequate formation for shallow foundations, the following steps need to be taken.

Step 1: Remove all existing waste material and highly compressible organic material from under the entire foundation footprint and an appropriate distance beyond its perimeter. Make due allowance for the removal of deeper pockets of unsuitable material.

Step 2: Backfill the footprint with new imported, selected 'shot rock' material to required elevations. Conduct vibro densification of the rockfill and the underlying Ironshore / 'marl' to achieve refusal of the vibrating 'poker' at the rock interface (using screened granular material as required by this process). Verify densification degree achieved by in-situ testing, in conjunction with the vibro specialist's analysis.

Step 3: Excavate the vibro-compacted fill under the future building footprint to achieve the elevations required for the building substructure.

Step 4: Proof roll the formation using 10-ton vibrating roller (40 passes min). The compacted layer is to be proof roll tested using a fully laden 22 cubic yard capacity twin axle dump truck.

The described ground improvement works predict the following parameters for foundation design (subject to trial, post-trial analysis and confirmation by vibro-compaction specialist).

- Allowable bearing capacity of up to 6,000 psf with a short term overstress of 25%.
- 1 - 1.5 inch total settlement and L/500 differential settlement limits.
- A subgrade modulus of 150 – 250 pounds per cubic inch (pci). This value may be varied depending on the results of recommended vibro-compaction trial. We recommend a sensitivity analysis be conducted by the structural engineer responsible for foundation analysis and design.

10.2 Option 2: Reinforced Concrete Continuous Flight Auger (CFA) Piles Supporting Reinforced Concrete Pile Caps

The second appropriate foundation system for the proposed structures would be the construction of an arrangement of reinforced concrete augercast piles supporting reinforced concrete pile caps and grade beams.

As part of these works, the existing waste material would need to be removed and replaced with selected granular material with no boulder sizes in excess of 9” such that the auger rig is not obstructed.

Sixteen (16) and twenty-four (24) inch diameter augercast piles bearing in the ‘limestone rock’ nominally at approximately 13ft below MSL are estimated to have an allowable compression load of 65 and 130 tons respectively, subject to confirmation by pile load testing. Piles in tension with a shaft length of a minimum of 20 ft minimum through competent Ironshore Formation ‘marl’ and compacted ‘shotrock’ have an uplift capacity of 25 tons for sixteen (16) inch diameter and 40 tons for a twenty-four (24) inch pile. The lateral load capacity is 10 tons and 17 tons respectively, based on fixed head condition. The above capacities are assuming a pile spacing of three (3) times the pile diameter. Care should be taken to ensure that the piles bear in the rock and not on a localized layer of dense 'marl’. Settlement of the piles is not expected to exceed 0.5 inch under design loads.

The auger rig shall drill into the rock until a refusal criterion of 2 inches per 30 minutes drilling at maximum torque. It is estimated that the pile embedment into the rock will be in the order of 6-8ft based on our experience to date.

Based on the preliminary building design with ground floor elevation at +11ft MSL and assuming a pile cap thickness of 4ft, the pile head would be at +7ft MSL. It can be expected that the pile embedment into the rock could be 6-8ft. Based on a typical rock elevation of -13ft MSL, the pile shaft length may be up to 30ft long.

Spring stiffness for the 24" diameter CFA piles can be taken as 600 kips/inch (300 tons/inch) from the load test results carried out for the ETH underpass and more recent projects.

It should be noted that significant grout loss is likely as the piles will be installed through the Ironshore Formation 'marl' and epikarst zones, and may encounter cavities at the rockhead. Redrilling and regrouting of piles may be needed in some instances. A useful advantage of the augercast pile is the system's facility to easily cater for the variable pile penetration lengths likely to be encountered on the site. Equipment with sufficient torque will be required to provide the required embedment in the rockhead.

Medium strength (5,000 pounds per square inch) grout should be tremied to fill the pile shaft under pressure. The concrete should be supplied from the bottom of the shaft and allowed to rise to expel ground water.

10.3 Foundations for Lightweight Structures

Municipal solid waste (MSW) is known to generally act in a homogenous nature in terms of response to imposed loading. It provides an allowable load bearing capacity that can be incorporated into the foundation design for lightweight buildings and ancillary structures with shallow foundations.

The general approach is to 'proof roll' the existing surface in compacted 9 inch lifts using a 10-ton vibrating roller (40 passes min) and later truck tested. Any soft areas identified during the truck test is to be demucked and backfilled under the direction of the Engineer. A minimum of 24 inches of well graded rockfill is to be placed in 9 inch lifts compacted to a minimum of 95% dry density.

Plate load compaction testing has indicated an allowable bearing capacity of at least 2,000psf can be achieved using the approach outlined above. Refer to **Addendums 1 & 2** for details on the testing completed on-site

10.4 Protection of Foundation Structures

A minimum of 5,000 pounds per square inch (psi) concrete and a maximum water/cement ratio of 0.4 is recommended for all reinforced concrete in contact with ground water. This is to ensure resistance to sulphate attack. Laboratory testing of the groundwater sample indicates that the sulphate level is consistent with seawater and can be characterized as 'moderate' per ACI 318.

10.5 Retaining Walls

The angle of internal friction of typical engineering fill available in Grand Cayman is 30 – 35 degrees. Refer to **Appendix C** for Dynamic Lateral Earth Pressure Coefficient design information for retaining walls.

11.0 CONCLUSIONS AND RECOMMENDATIONS

11.1 GENERAL

The proposed development comprises an Energy Recovery Facility (ERF) on the site of a proposed Integrated Solid Waste Management System (ISWMS) Facility. The site is part of a historic municipal landfill with existing ground elevations ranging from approximately 2 ft to 12 ft MSL. Twenty-six trial pits and fifteen boreholes were advanced on the site between November and December, 2020 under APEC's supervision.

The subsoil conditions encountered during the investigation were generally consistent across the site. The subsoils encountered included up to 16 feet of topsoil/ 'marl' / municipal waste mix. This mixed fill material is superjacent to native Ironshore Formation 'marl' at approximately 0 - 2 ft below MSL. Highly compressible organic material was encountered in some trial pits and boreholes typically between -2 ft and +2 ft MSL. 'Limestone bedrock' was encountered at between 15 and 24.5 ft BGL (10 and 13.5 ft below MSL) in the boreholes. A number of cavities were encountered within the Ironshore Formation, the epikarst zone and the limestone rock stratum.

The stabilized ground water elevation on the site during Mean High Water Spring (MHWS) tide is estimated to be approximately 2.0 ft above MSL. The groundwater ingress into the trial pits was noted as being slow.

11.2 RECOMMENDATIONS FOR SUITABLE FOUNDATION SYSTEMS FOR THE BUILDING

Two options are provided for consideration for the foundation systems for the proposed ERF structures.

Option 1 - Demuck/backfill/vibro densification

This option involves the removal of all existing mixed fill and compressible organic material from under the entire foundation footprint of the ERF building and to an appropriate distance beyond its perimeter. The depth of excavation should extend to a minimum of 16 ft below existing ground levels and extend into the Ironshore Formation. Allowance should be made for deep pockets of unsuitable material (waste fill mix and / or highly compressible organics). The footprint would then be backfilled using imported 'shot rock' selected from local quarries and vibro densification of the rockfill carried out by a reputable and experienced groundworks specialist company.

It is predicted - subject to a field trial by the vibro compaction specialist contractor - the vibro compaction technique will provide the following parameters for foundation design:

- Allowable bearing capacity of up to 6,000 psf with a short term overstress of 25%.
- 1 - 1.5 inch total settlement and L/500 differential settlement limits.
- A subgrade modulus of 150 – 250 pounds per cubic inch (pci). This value may be varied depending on the results of recommended vibro compaction trial. We recommend a sensitivity analysis be conducted by the structural engineer responsible for foundation analysis and design.

Option 2 - The installation of reinforced concrete continuous flight auger (CFA) piles supporting reinforced concrete pile caps.

Sixteen (16) and twenty-four (24) inch diameter augercast piles bearing in the 'limestone rock' nominally at approximately 13ft below MSL are estimated to have a compression load ranging from 65 to 130 tons respectively, subject to confirmation by pile load testing. Piles in tension with a shaft length of a minimum of 20 ft minimum through competent Ironshore Formation 'marl' and compacted 'shotrock' have an uplift capacity of 25 tons for sixteen (16) inch diameter and 40 tons for a twenty-four (24) inch pile. The lateral load capacity is 10 tons and 17 tons respectively, based on fixed head condition. The above capacities are assuming a pile spacing of three (3) times the pile diameter. Care should be taken to ensure that the piles bear in the rock and not on a localized layer of dense 'marl'. Settlement of the piles is not expected to exceed 0.5 inch under design loads.

Spring stiffness for the CFA piles can be taken as 600 kips/inch (300 tons/inch) from the load test results carried out for the ETH overpass.

Significant grout loss may be likely as the piles will be installed through the epikarst zone which we noted as extending up to 8 ft above the nominal 'bedrock' level. Redrilling and regrouting of piles may be needed in some instances. Equipment with sufficient torque will be needed to provide the required embedment.

It is understood from the Director of Planning and based on the requirements of the Cayman Islands Building Code that Special Structural Inspections will be required for the foundation testing and construction of this structure.

11.3 Foundations for Lightweight Structures

Shallow foundations are recommended for lightweight buildings and ancillary structures at the ISWMS site. The existing MSW & soil should be 'proof rolled' in compacted 9 inch lifts using a 10-ton vibrating roller (40 passes min) and later truck tested. Any soft areas identified during the truck test is to be demucked and backfilled under the direction of the Engineer. A minimum of 24 inches of well graded rockfill is to be placed in 9 inch lifts compacted to a minimum of 95% dry density.

Plate load testing has confirmed an allowable bearing capacity of 2,000psf can be achieved.

11.4 Protection of Foundation Structures

Reinforced concrete in direct contact with the ground water should have a minimum strength of 5,000 psi and a maximum water-cement ratio of 0.4. Reinforcement should have adequate cover.

11.5 Environmental Considerations

Hurricane related sea surge and flooding could occur on the site during the life of the development from either the North Sound to the east or from the Caribbean Sea to the west. Based on the currently available information, the 100-year base flood elevation for the site is 9 feet MSL (refer to **Section 5.0** for details).

DESIGN FLOOD ELEVATION REVIEW

Client:	Dart Ltd PO Box 772 Grand Cayman KY1-9006	**Job:**	Integrated Solid Waste Management Facility Block 13D / Parcel 431 George Town, Grand Cayman
Attn:	Finley Joseph & Naomi Law		
		Date:	August 5, 2020

1.0 INTRODUCTION & BACKGROUND

APEC has been asked to review the design flood elevations (DFEs) for a proposed integrated solid waste management system (ISWMS) facility to be located on parcel 13D431. Refer to **Figure 1**.

FIGURE 1: PROPOSED LOCATION FOR SOLID WASTE MANAGEMENT FACILITY

The Cayman Islands does not currently have established Flood Insurance Study (FIS) reports or FEMA flood maps (FIRMS). In the absence of these, APEC has been referencing the documented Hurricane Ivan flood data which equates approximately to the 100 year design flood event. The Cayman Islands Lands & Survey Department Hurricane Ivan flood map reports a stillwater flood elevation in excess of 8ft MSL in this area. This is consistent with readings APEC took in the aftermath of Hurricane Ivan at the neighbouring Camana Bay site. It is noteworthy that the stillwater flood elevations depicted on the flood map for this area of George Town are representative of severe flooding due to a 100 year event which is partly dependant on the storm's track. Ivan's westerly track to the south of Grand Cayman and the anticlockwise motion of its winds forced a large volume of seawater into the shallow North Sound which resulted in the worst flooding on Island to occur in the industrial park area of Cayman.

APEC Consulting Engineers Ltd
PO Box 10118, Grand Cayman KY1-1001, Cayman Islands

2.0 DETERMINATION OF THE NEW SITE DESIGN FLOOD ELEVATIONS

The proposed new facility is approximately 3,000ft inland from the North Sound. It is protected by the George Town Landfill's (GTLF) south mound, which reaches 44ft MSL in height. It is also flanked to the north by the GTLF's North Mound (at over 80ft MSL), and east & south with industrial development. The backshore is not conducive to maintaining significant wave action at this site from either the North Sound or the Caribbean Sea to the west. This would put the site under an **A** zone under the FEMA classification (refer to **Figure 2**), i.e. expected to be subjected to stillwater flooding only during a 100 year flood event. The base flood elevation (BFE) was therefore calculated as follows:

Existing Ground Elevation =	~4ft MSL
100 year flood, d100 =	8.5 – 4 = 4.5 ft (Hurricane Ivan stillwater readings)
Wave Crest, 0.55*d100 =	~0.5
BFE = 8.5+2.5 =	**+9 ft MSL**

ASCE Standard 24 for Flood Resistant Design and Construction gives guidance for determining the DFE based on building occupancy categories.

DFE for Occupancy Categories on 13D431

Occupancy Category I buildings (e.g. agri. buildings, storage sheds) = BFE	**+9ft MSL**
Occupancy Category II buildings (all other buildings.) = BFE + 1ft	**+10ft MSL**
Occupancy Category III & IV (essential facility, public assembly, etc.) = BFE + 2ft	**+11ft MSL**

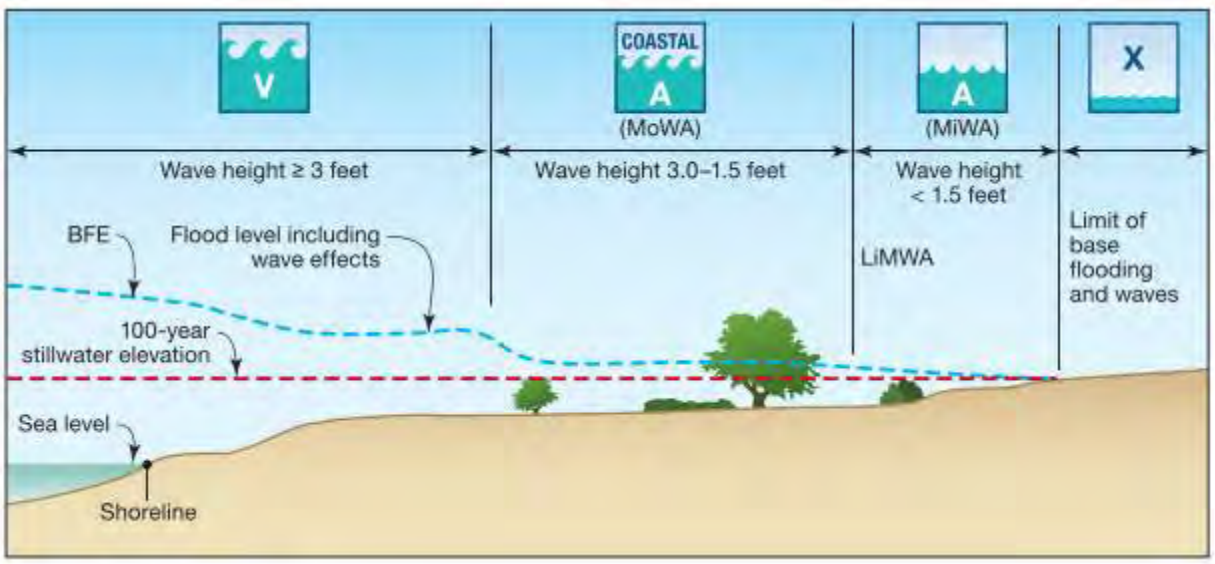

FIGURE 2: FEMA COASTAL ZONES

APEC Consulting Engineers Ltd
PO Box 10118, Grand Cayman KY1-1001, Cayman Islands

3.0 REVIEW OF ISWMF BUILDING FLOOR ELEVATIONS

Below is a summary of the various buildings at the proposed ISWMF with their occupancy category in accordance with the 2009 International Building Code (IBC) and associated DFEs.

ISWMF BUILDING	DESCRIPTION	OCCUPANCY CATEGORY	DFE (ft MSL)
WEIGHBRIDGE	OPERATOR'S OFFICE	II	10
HOUSEHOLD WASTE PROCESSING	STAFF FACILITIES & WORKSHOP	II	10
ELV FACILITY	STAFF FACILITIES	II	10
MRF	SHED WITH PROCESSING EQUIPMENT	I	9
ADMINISTRATION	OFFICES, STAFF FACILITITES	II	10
MAINTENANCE FACILITY	STAFF FACILITIES	II	10
BA PROCESSING	SHED WITH PROCESSING EQUIPMENT	I	9
ENERGY RECOVERY FACILITY	POWER GENERATION PLANT	III	11

In some cases the processing buildings do include small staff facilities such as restrooms, break rooms & associated equipment rooms. These rooms can be locally elevated to provide an Occupancy Category II DFE.

It is worth noting that the building DFEs do not require the surrounding hardscape to be elevated to similar levels. Final site elevations will be dictated by the requirements for transporting processing and disposing of the waste and how the buildings interact with the various processes.

APPENDIX C – DYNAMIC LATERAL EARTH PRESSURE COEFFICIENT

APEC Consulting Engineers Ltd
PO Box 10118 Grand Cayman KY1-1001 Cayman Islands
Ph: (345) 949-5858 E-mail: apec@apec.com.ky

Calculation of Dynamic Lateral Earth Pressure Coefficient:

Method – Monobe-Okabe (M-O) as modified by Seed and Whitman.

$P_{AE} = P_A + \Delta P_{AE}$

$K_{AE} = K_A + \Delta K_{AE}$

$\Delta P_{AE} = (1/2)\ \gamma\ H^2\ \Delta K_{AE}$

$\Delta K_{AE} = 0.75\ K_h$

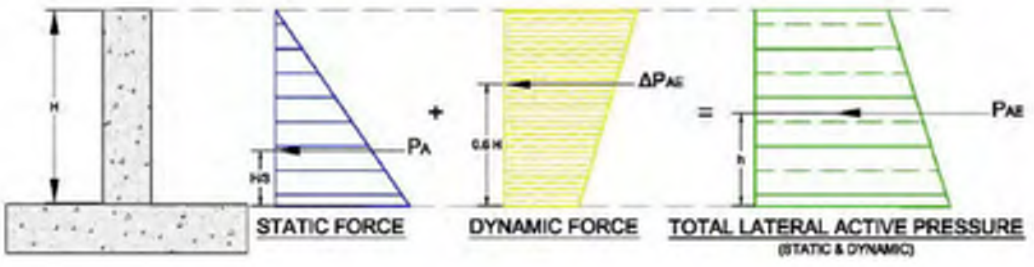
$\Delta P_{AE} = 0.5\ \gamma\ H^2 \times 0.75\ K_h$

Where:

P_{AE}: The total (static + dynamic) lateral thrust

γ is unit weight of backfill soil

H is height of backfill behind the wall



K_{AE} is the static plus dynamic lateral earth pressure coefficient

K_A is the static lateral earth pressure coefficient

ΔK_{AE} is the dynamic lateral earth pressure coefficient

K_h is the horizontal seismic ground acceleration component and can be taken as 0.5 (S_{DS}/2.5) for yielding retaining walls or (S_{DS}/2.5) for a restrained retaining wall

For the distribution of the dynamic thrust, ΔP_{AE}, the resultant dynamic thrust act at 0.6H above the base of the wall (that is, inverted trapezoidal pressure distribution). Assume no hydrostatic pressure for seismic condition.

Lateral Pressure Diagram Example

ADDENDUM – PLATE LOAD TESTING & TRIAL PITS

A.1 PLATE LOAD TESTING

Four Plate Load Tests (PLT) were carried out on February 27, 2023 - two of the PLT's were located within CW.09, the residual waste landfill area, and two were located within CW.03, the end-of-life vehicle (ELV) facility. At each test location one loading point was measured at grade level.

PLT is used to determine load settlement lines which are used to evaluate the deformability and the bearing capacity of the soil. During testing, a circular load plate (300mm in diameter) is repeatedly loaded and relieved by means of a load device consisting of a hydraulic pump and pneumatic cylinder. The load is applied to the plate in 6 to 8 equal loading steps. The settlement of the plate is measured by the tester consisting of a carrier frame with a sensing arm and dial gauge. As a counterbalance, a heavy-weight vehicle is used – during testing the CAT 330 tracked excavator was used for this. **Figure A1** shows the PLT set-up used on site.

The indentation of the load plate into the soil, generated with every load step, is indicated on a dial gauge. The settlement of every load step and the corresponding mean normal stress below the load plate appear as test values. Subsequent to the last load step the relief and a second loading similar to the first loading takes place. For the test evaluation these values are plotted as load settlement lines.

FIGURE A1 – PLT USING CAT330 AXEL AS COUNTERBALANCE

The modulus of deformation, Ev, is determined from the load settlement line of the first load (Ev1) and the second load (Ev2). The degree of settlement attained is determined by comparing the initial deformation from Ev1 and the subsequent deformation of Ev2. Refer to **Appendix D** for test results.

A.2 TRIAL PITS

APEC completed Trial Pits 21 to 24 on February 2nd within CW.09, the future expansion area. These trial pits formed part of the original geotechnical investigation plan however could not be complete at the time as the areas were inaccessible. Refer to drawing S1-01 Rev 4 for the trial pit locations and SK17 Rev 1 for the trial

pit logs. **Table A1** below summarizes the results of the Trial Pits 21, 22 and 23. Trial Pit 24 contained 7.5 feet of rock fill superjacent to the Ironshore Formation 'marl'. Trial pitting was carried out using a CAT 330L tracked excavator which could not penetrate the caprock of the Ironshore Formation 'marl' encountered underlying the fill material in all trial pits.

Strata	Approx. thickness/ elevation
Topsoil 'Marl' fill and municipal waste mix	Surface elevation varies from 3 to 6.25ft MSL Thickness 5 to 8.5ft
'Marl' (Ironshore Formation) Caprock	Excavator could not penetrate
Ground water	Ground water level varies average of 2ft MSL*

*average levels measured within trial pits, variation tidally influenced

TABLE A1 – SOIL PROFILE SUMMARY

A.3 ALLOWABLE BEARING CAPACITY

The bearing capacities from the PLT results are considered high with values of greater than 10,000 PSF noted in three of the four test areas. The values obtained have been rationalized by assuming that the maximum test value obtained within the engineered rock fill in CW.02, the ELV facility, is 4,000 psf and all test results then calculated relative to this figure to provide allowable bearing capacities (ABC). Using this conservative approach, we get ABC's of approximately 4,000 psf in test areas 2, 3 and 4. Test area 1 returns an ABC of 1,280 psf, the soil profile in the vicinity of this test area is approximately 6 feet of topsoil 'marl' fill and municipal waste mix over the Ironshore Formation.

ADDENDUM 2 – GAS FLARE COMPOUND

B.1 INTODUCTION

The proposed gas flare compound is located along the northern boundary of the GT Landfill's south mound. See **Figure 1**. It is located in an area which was mined of limestone 'marl' and backfilled with municipal solid wate (MSW) sometime in the 1980s. We understand the south mound has been left inert with a soil cap for over 30 years.

The preliminary design for the compound indicates a gas flare stack on shallow reinforced concrete foundations on a minimum of 2 feet engineered rockfill. The total depth of rockfill varies, as the compound will be levelled to a minimum elevation of 12ft MSL.

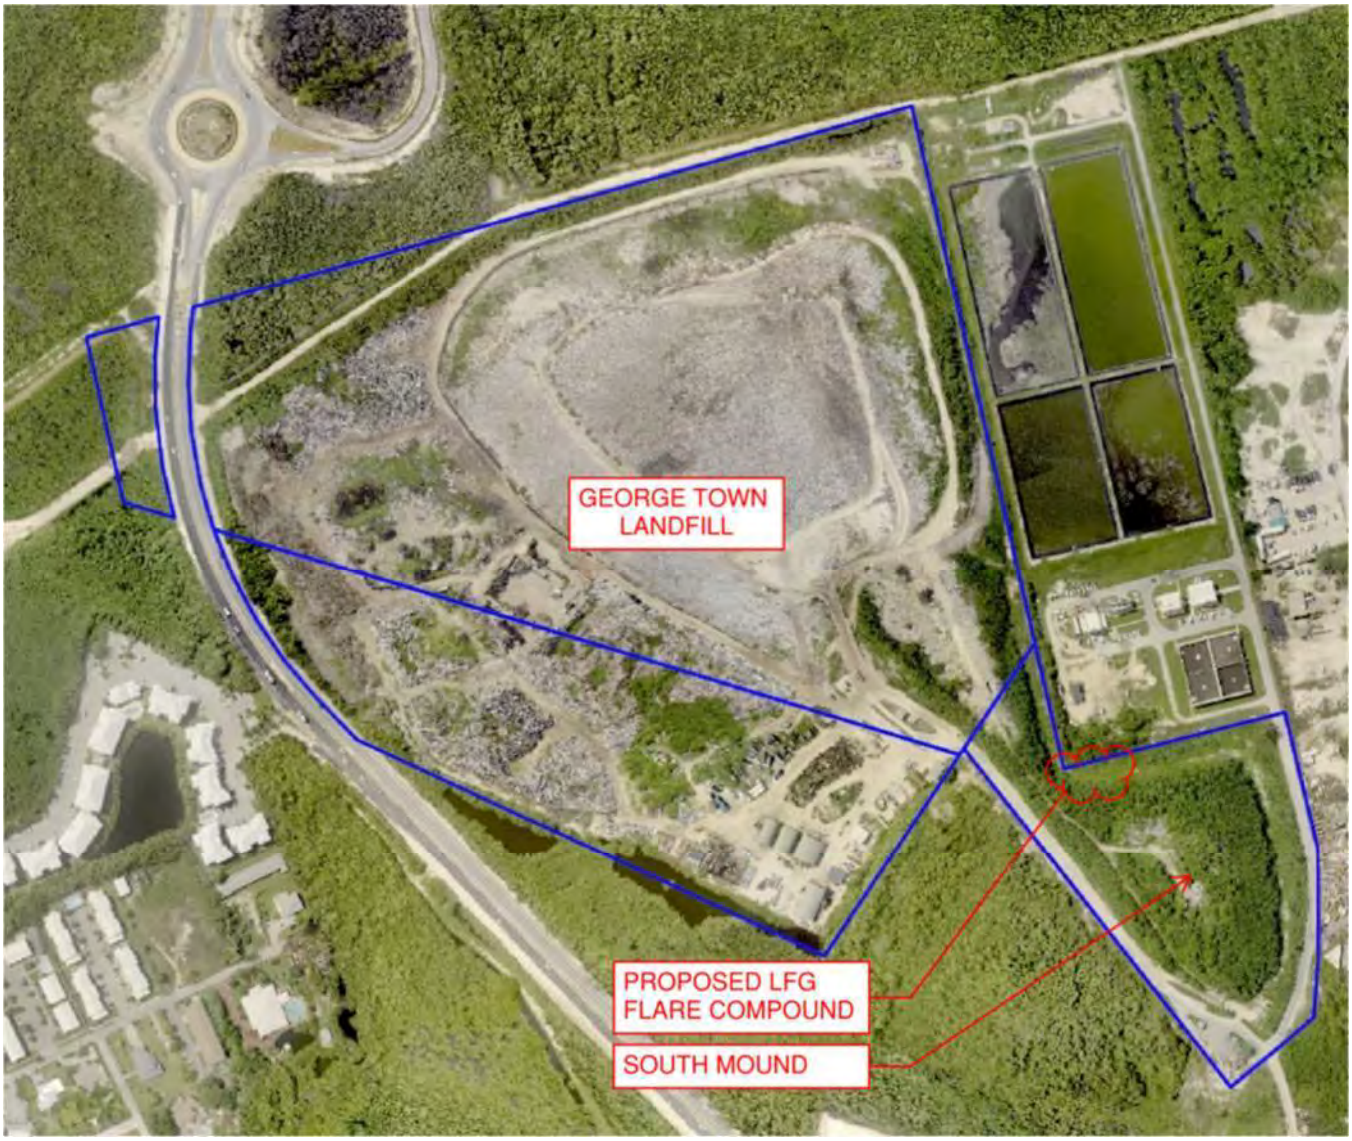

FIGURE 1: GEORGE TOWN LANDFILL AND PROPOSED GAS FLARE IDENTIFIED (2018 LANDS AND SURVEY AERIAL)

B.2 TRIAL PITS

APEC completed Trial Pits 33 to 35 on 12th April 2023 within CW.17, the landfill gas treatment area. These trial pits formed part of the original geotechnical investigation plan however could not be completed at the time as the areas were inaccessible. Refer to drawing SI-01 Rev 6 for the trial pit locations and SK-17 for the trial pit logs. **Table 1** below summarizes the results of Trial Pits 33 to 35. Trial pitting was carried out using a Hitachi 350 tracked excavator which could not penetrate the caprock of the Ironshore Formation 'marl' encountered underlying the fill material in all trial pits.

Strata	Approx. thickness/ elevation
Topsoil 'Marl' fill and municipal waste mix	Surface elevation varies from 7.5 to 15.75ft MSL Thickness 10 to 13ft
'Marl' (Ironshore Formation) Caprock	Excavator could not penetrate
Ground water	Ground water level varies average of 2ft MSL*

*average levels measured within trial pits, variation tidally influenced

TABLE 1 – SOIL PROFILE SUMMARY

FIGURE 2: TRIAL PIT TP-33

B.3 PLATE LOAD TESTING

Three Plate Load Tests (PLT) were carried out on May 4th 2023 - all of the PLTs were located within CW.17. A fourth PLT was completed in the industrial estate in an area with no MSW present on May 24th 2023. This was used as a control test for comparative purposes. At each test location one loading point was measured at grade level.

PLT is used to determine load settlement lines which are used to evaluate the deformability and the bearing capacity of the soil. During testing, a circular load plate (300mm in diameter) is repeatedly loaded and relieved by means of a load device consisting of a hydraulic pump and pneumatic cylinder. The load is applied to the plate in 6 to 8 equal loading steps. The settlement of the plate is measured by the tester consisting of a carrier frame with a sensing arm and dial gauge. As a counterbalance, a heavy-weight vehicle is used – during testing a tracked excavator was used for this purpose. **Figure 3** shows the PLT set-up used on site.

The indentation of the load plate into the soil, generated with every load step, is indicated on a dial gauge. The settlement of every load step and the corresponding mean normal stress below the load plate appear as test values. Subsequent to the last load step the load relief and a second loading similar to the first loading takes place. For the test evaluation these values are plotted as load settlement lines.

The modulus of deformation, Ev, is determined from the load settlement line of the first load (Ev1) and the second load (Ev2). The degree of settlement attained is determined by comparing the initial deformation from Ev1 and the subsequent deformation of Ev2. Refer to the end of this addendum for test results.

FIGURE 3: PLATE LOAD TEST

B.4 ALLOWABLE BEARING CAPACITY

The allowable bearing capacities (ABC) from the PLT results are considered as medium capacities for soil with values of greater than 5,000 PSF noted in two of the three test areas. The values obtained have been rationalized by assuming that the maximum test value obtained from the 'control' test in the industrial estate on limestone 'marl', is 4,000 psf and all test results then calculated relative to this figure. Using this conservative approach, we get ABC's of approximately 2,000 psf in test areas 6 and 7. Test area 5 officially failed, with an ABC of approximately 1,000psf.

We recommend an ABC of 2,000 psf is taken for the proposed foundations within the gas flare compound. Any areas of obvious soft spots (e.g. test area 5) should be removed and backfilled with well graded engineered rockfill compacted in lifts not exceeding 12 inches. It is worth noting however that test areas 6 and 7 were proximate to the proposed gas flare stack and equipment pads.

Terminology

Terminology	Definition
Aesthetics	Relating to the sense of the beautiful or science of aesthetics, i.e., the deduction, from nature and taste, the rules, and principles of beauty.
Impact	The effect of a proposal, which can be adverse or beneficial, when measured against an existing condition.
Landscape	All aspects of a tract of land, including landform, vegetation, buildings, villages, towns, cities, and infrastructure.
Landscape character	The combined quality of built, natural and cultural aspects which make up an area and provide its unique sense of place.
Landscape character zone	An area of landscape with similar properties or strongly defined spatial qualities, distinct from areas immediately nearby.
Magnitude	The measurement of the scale, form and character of a development proposal when compared to the existing condition. In the case of visual assessment this also relates to how far the proposal is from the viewer. Combines with sensitivity, magnitude provides a measurement of impact.
Project	The construction and operation of the Integrated Solid Waste Management Facility (ISWMS) Project
Project area	The area within which all the Project construction and operational elements will be contained within.
Seascape character	An area of land, coastline, and sea whose combined interactions define an area
Seascape character zone	A specific locality compromising defined attributes and characteristics distinct from neighbouring areas.
Sensitivity	The sensitivity of a landscape character zone or view and its capacity to absorb change of the nature of the Project. In the case of visual impact this also relates to the type of viewer and number of viewers. Combined with magnitude, sensitivity provides a measurement of impact. Viewpoint The point from which a view is observed that represents a visual receiver. Viewshed The area within which a project can be seen at eye level above ground. Its extent will usually be defined by a combination of landform, vegetation and built elements
Significant	In the context of Environmental Impact Assessment, after analysing the extent (type, size, scope, intensity, and duration) and nature (predictability, resilience of the environment, reversibility, ability to manage/mitigate, level of public interest) of a proposal, an expected level of impact of a proposal which requires an EIS to be undertaken. The term should be avoided in landscape character and visual impact assessments if the expected level of impacts is below the threshold.
Study area	Consists of land in the vicinity of, and including, the Project site. The study area is a wider area surrounding the Project site as defined in this assessment, including land that has the potential to be indirectly impacted by the Project.
View	The sight or prospect of a landscape or scene.
Viewpoint	The point from which a view is observed that represents a visual receiver.
Viewshed	The area within which a project can be seen at eye level above ground. Its extent will usually be defined by a combination of landform, vegetation and built elements.
Visibility	The state or fact of being visible or seen.
Visual effect	The effect on the views from residences, workplaces, and public place
Visual receiver	A selected location of view representing a visual receiver.
Zone of Theoretical Visibility	A map, usually digitally produced, showing areas of land within which, a development is theoretically visible.

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

1. Introduction

1.1 Overview

The proposed ISWMS Site is located to the north of central George Town towards the western coast of Grand Cayman, immediately south-west of the existing George Town Landfill (GTLF).

The proposed ISWMS development consists of various new waste management facilities. The various components of the ISWMS subject to assessment in the *Terrestrial Ecology Assessment – Existing Conditions Report* are as follows:

– Energy Recovery Facility
– Non-Energy Recovery Facilities:
  - Green Waste Processing Facility
  - Construction and Demolition Waste Processing Facility
  - Bottom Ash Processing Facility
  - Abandoned and End-of-Life / Scrap Metal Processing Facility
  - Medical Waste Facility
  - Landfill Gas Facility
  - Residual Waste Landfill (RWL)

The design life of the new facilities is 25 years.

1.2 Purpose of this report

The Cayman Islands Government in partnership with DECCO Consortium (the Proponent) is proposing to develop an Integrated Solid Waste Management Facility (ISWMS) in the Cayman Islands, on Grand Cayman ('the Project'). The Seascape and Landscape Visual Considerations Report consist of two related assessments that assess effects of the construction and operation of the proposed ISWMS on the landscape, concentrating upon effects upon the landscape and townscape character, and effects upon the views and visual amenity of people who live, undertake recreational activities, work and/or travel through the area around the proposed ISWMS on the western side of Grand Cayman.

1.3 Report structure

The report is comprised of the following sections:

Section 1 - Introduction: provides background information and an overview of the project and assessment.

Section 2 - Methodology: describes the methodology used for the purpose of this report.

Section 3 - Proposal description: describes the proposed development, with emphasis on identifying the key sources of potential effects relevant to this assessment.

Section 4 - Legislation and policy: provides an overview of relevant legislation and policy.

Section 5 - Existing environment: provides an overview and describes the landscape and visual environment within the study area.

Section 6 - Landscape character assessment: landscape character zones are identified and assessed against the proposed development.

Section 7 - Visual consideration assessment: representative viewpoint locations are identified and assessed against the proposed development.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Section 9 – Mitigation measures: recommendations and mitigation measures are provided in response to identified effects as a result of the construction and operation of the project.

Section 10 Conclusion presents a summary of the Seascape and Landscape Visual Considerations Report.

1.4 Scope and limitations

This report: has been prepared by GHD for ReGen and the Cayman Islands Government and may only be used and relied on by ReGen and the Cayman Islands Government for the purpose agreed between GHD and ReGen and the Cayman Islands Government as set out in this report.

GHD otherwise disclaims responsibility to any person other than ReGen and the Cayman Islands Government arising in connection with this report. GHD also excludes implied warranties and conditions, to the extent legally permissible.

The services undertaken by GHD in connection with preparing this report were limited to those specifically detailed in the report and are subject to the scope limitations set out in the report.

The opinions, conclusions and any recommendations in this report are based on conditions encountered and information reviewed at the date of preparation of the report. GHD has no responsibility or obligation to update this report to account for events or changes occurring subsequent to the date that the report was prepared.

The opinions, conclusions and any recommendations in this report are based on assumptions made by GHD described in this report (refer section(s) 1.5 of this report). GHD disclaims liability arising from any of the assumptions being incorrect.

GHD has prepared this report on the basis of information provided by ReGen and the Cayman Islands Government and others who provided information to GHD (including Government authorities), which GHD has not independently verified or checked beyond the agreed scope of work. GHD does not accept liability in connection with such unverified information, including errors and omissions in the report which were caused by errors or omissions in that information.

1.5 Assumptions

The methodology includes the following assumptions and limitations:

- There is no national guidance on the assessment of landscape and visual impacts specific to Cayman Islands, however, the industry typically refers to the guidelines as outlined in Section 2.1.
- The assessment aims to be objective and describe any changes factually. While potential changes resulting from the proposal are defined, the significance of these changes requires qualitative (subjective) judgements. This assessment's conclusion therefore combines objective measurement and professional interpretation. While this assessment aims to be objective, it is recognised that visual impact assessment can be subjective, and individuals are likely to associate different visual experiences to the study area.
- The assessment is based on the information provided to GHD at the time of writing.
- This assessment does not include landscape and visual effects from lighting.
- The authors of this report have not carried out the site visit as it was conducted by other within GHD.
- Detailed terrain data was unable to be obtained from the Lands and Survey Department, which is a limitation of the assessment.
- Visualisations were conducted by subconsultants OLA of 1270 Fulton Street #3, Brooklyn, New York. These are Artistic Impressions only and do not meet the LVIA technical photomontage standards as set out in *"The Landscape Institute Advice Note 06/19 Visual Representation of Development Proposals".* These artistic impressions are approximate and produced without appropriately accurate geolocation and topography data and therefore should not be relied upon for a LVIA visual impact assessment.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

2. Methodology

2.1 Standards and guidance

This LVIA chapter has been prepared within the spirit and intent of the ISWMS Terms Of Reference (TOR) however the methodology slightly deviates from the GLVIA guidance below, due to the visual impact specialists not attending site and artistic impressions being provided using a non-standard methodology:

– *Guidelines for Landscape and Visual Impact Assessment, 3rd Edition (Landscape Institute and Institute of Environmental Management & Assessment, 2013)* ('GLVIA3')

2.2 Study area

The Seascape and Landscape Visual Considerations Report study area (the 'study area') for the Project extends 3 miles (4.8 kilometres [km]) which was rounded up to five km from the ISWMS site boundary, see Figure 1 Study Area.

This study area has been used for the purposes of data collection and the subsequent assessment and has been defined to ensure that the LVIA concentrates upon receptors that are most likely to be significantly affected by the Project. It is derived from a review of the Final EIA Terms of Reference for a Cruise Birthing Terminal that was proposed for George Town[1]. It is considered that the height of the proposed Project is broadly comparable to the height of cruise ships and that the baseline topography will be comparable given both developments are located in western Grand Cayman. The extent of the study area also reflects the assessors' experience of undertaking LVIAs for similar developments.

The study area accords with best practice, as set out in Sections 5.2 and 6.2 in GLVIA3, as well as the principle of proportionality set out in paragraph 3.16: "The level of detail provided should be that which is reasonably required to assess the likely significant effects. It should be appropriate and proportional to the scale and type of development and the type and significance of the landscape and visual effects likely to occur."

[1] Mott Macdonald for the Government of the Cayman Islands (2013). Final EIA Terms of Reference for Cruise Berthing Terminal for the Cayman Islands.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

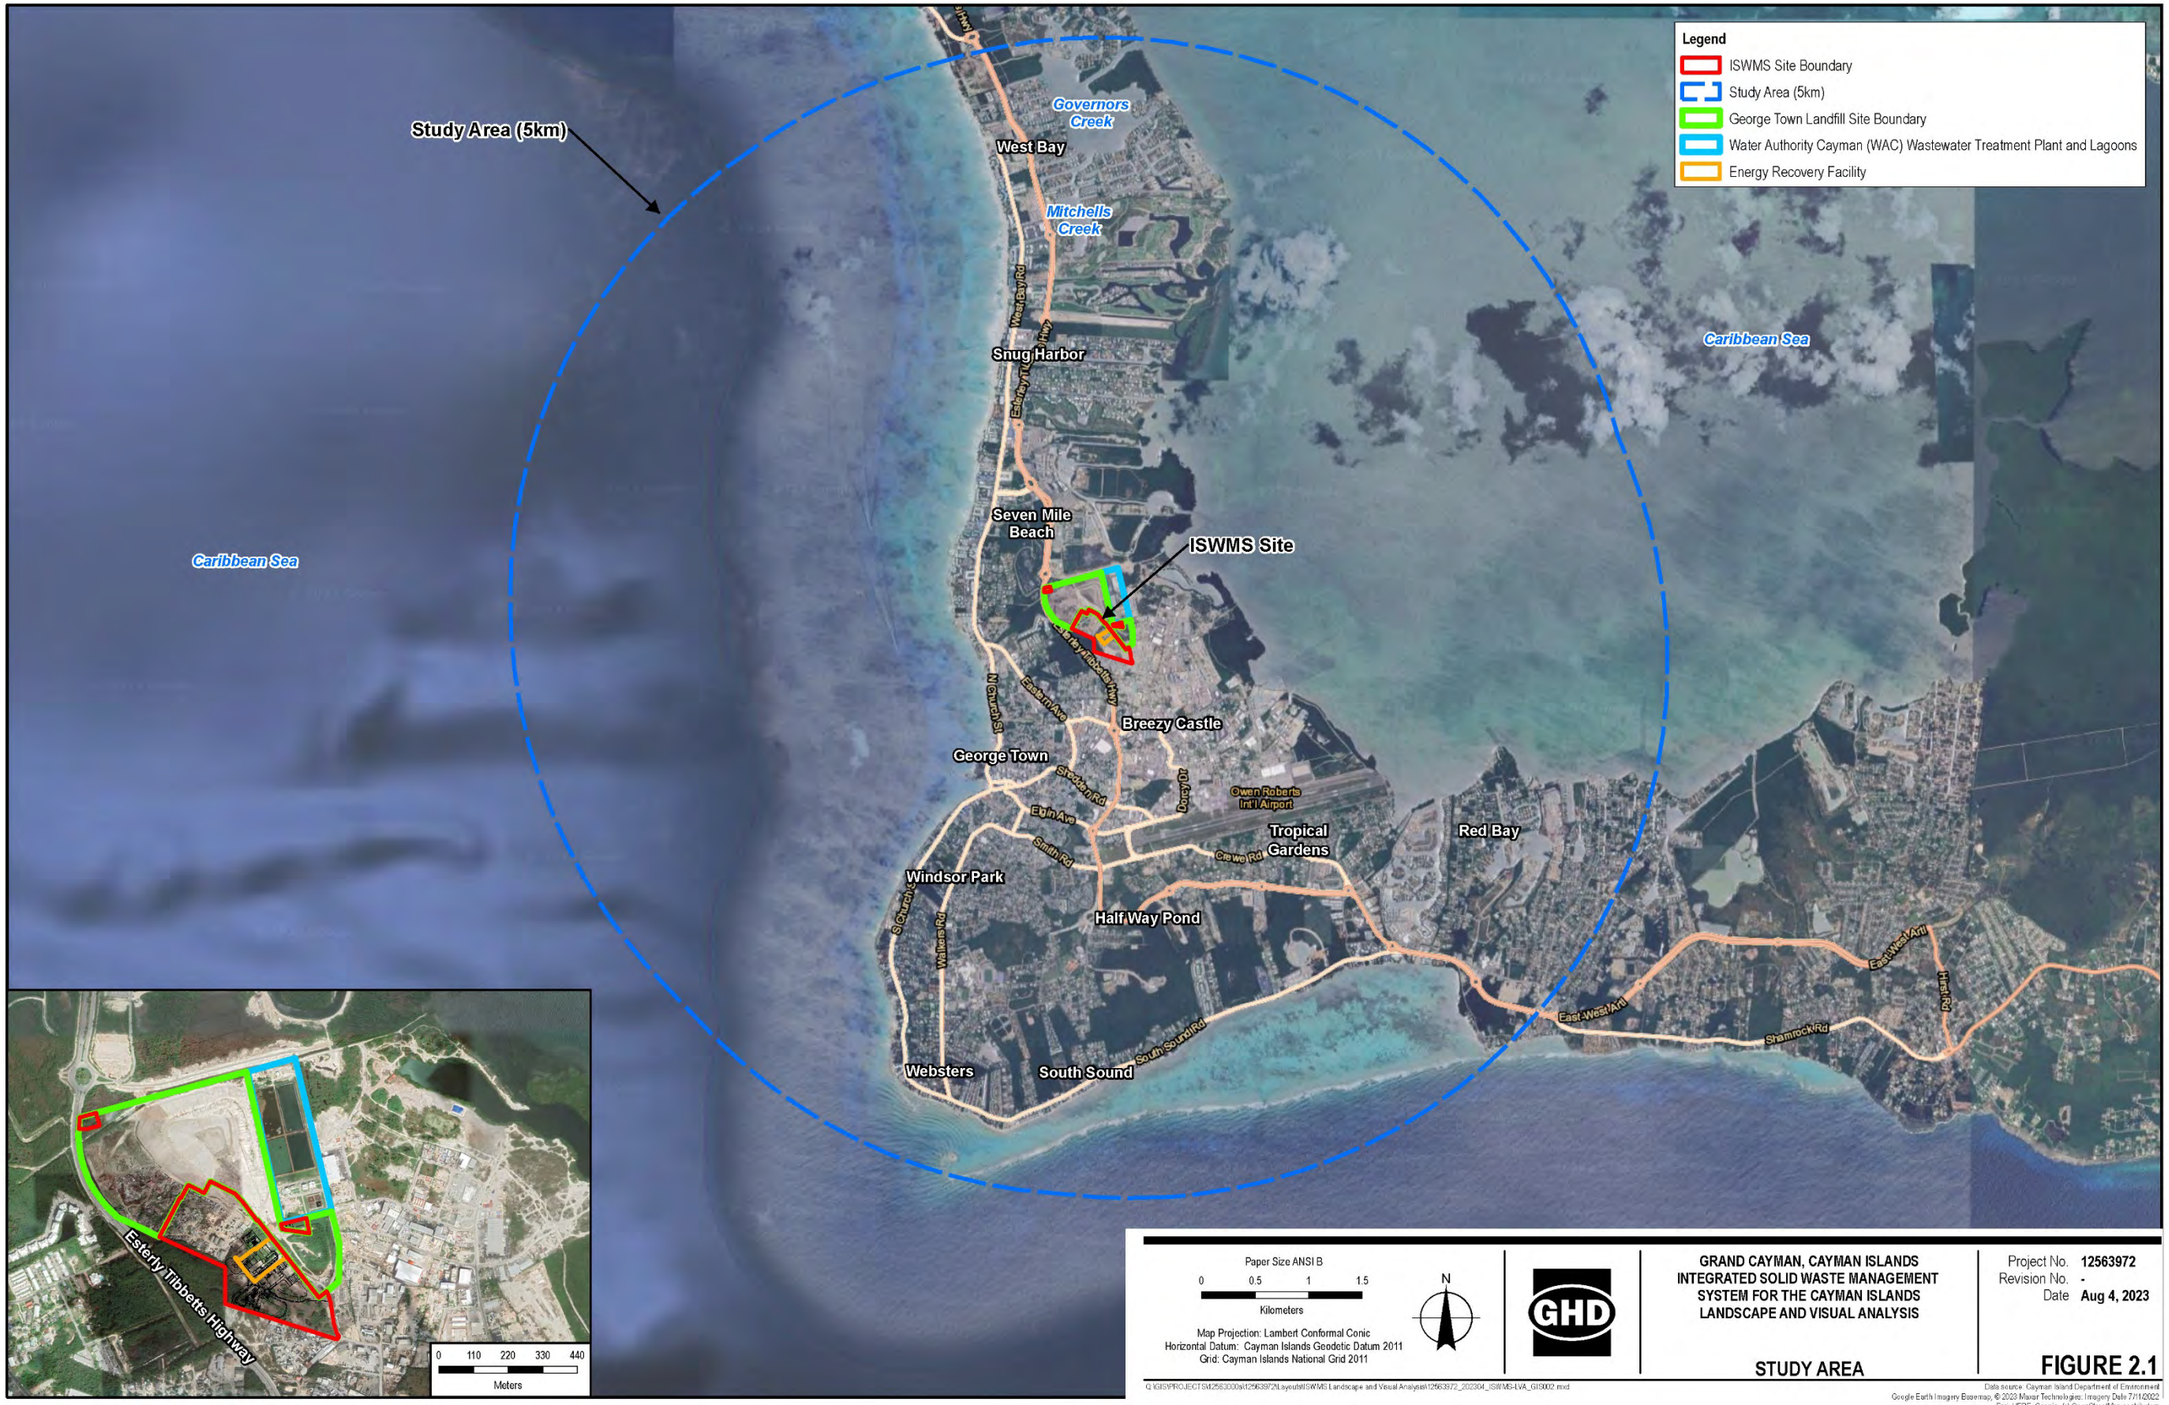

Figure 1 Study area

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

2.3 Existing landscape and visual environment

2.3.1 Review of legislation and policy

A review of key planning designations, policies and guidance was undertaken in relation to landscape and visual amenity within the study area. The emphasis of the review was to identify elements outlined within legislation, policy, and planning documents relevant to landscape and visual character and identity of the study area.

2.3.2 Desktop analysis

Existing data was gathered and reviewed for the Project, including the following landscape and visual resources:

– Project design information and site photographs
– Land use and vegetation maps
– Aerial imagery, Google Earth, and Google Street View

Using this data, a preliminary assessment of the landscape and visual environment was undertaken to inform the site inspection. Due to the data availability constraints, topographical data was unable to be obtained.

2.3.3 Zone of Theoretical Visibility assessment

Zone of theoretical visibility (ZTV) mapping is computer-generated analysis which identifies land from which it is theoretically possible to view the components of the Project.

Separate ZTV maps have not been calculated for the project due to the lack of available terrain data. Based upon desktop studies which emphasise the flat topography of western Grand Cayman, it is highly likely that a ZTV calculated using bare earth digital terrain data would extend across all the land and sea within the study area, due to the low-lying topography and long views.

The proposed ISWMS will potentially be visible as the stack has a height of 48.1 m (158 feet) above ground level (AGL) and will likely be the tallest component in the study area. The ERF has heights of between 37.8 m AGL (124 feet) for the boiler house and 33.4 m AGL (110 feet) for the waste bunker. These are likely to be the tallest and therefore the most visible components within the overall proposed project.

The data gathering methodology has been restricted to a desk study utilising a variety of websites, including:

– Visitcaymanislands.com – identification of principal tourist destinations in western Grand Cayman.
– En.wikipedia.org – general information and details of National Trust properties.
– Academic.emporia.edu – information on geology and topography.
– Brahmsonline.kew.org/cayman – information on geology and vegetation types.
– Camanabay.com – information upon tourist development and associated landscape planting in western Grand Cayman.
– Familyvacationcritic.com – for information on the height and accessibility of the Camana Bay Observation Tower.
– Review of baseline information in Final EIA Terms of Reference for a Cruise Ship Berthing Terminal; and
– Review of aerial photography:
    - Imagery dated 21 November 2018 from Google Earth Pro; and
    - Updated imagery from Bing Maps and Google Maps.

2.3.4 Site inspection

A site inspection was undertaken by GHD staff on 19th of April 2023. The purpose of the inspection was to:

– Inspect the site and appreciate views to / from sensitive visual receivers.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

– Inspect publicly accessible locations identified in the desktop study as likely to provide views of the Project.
– Identify sensitive visual receiver locations.
– Assess the landscape character of the study area and identify landscape sensitivities.
– Undertake site photography suitable for viewpoint assessment and artistic impression preparation.

The coordinates of each viewpoint were recorded during the site inspection.

2.3.5 Description of existing seascape, landscape, and visual environment

The description of the existing seascape, landscape and visual environment establishes a baseline against which the project is assessed. An existing conditions assessment was undertaken to determine the existing natural and cultural features within the study area. This includes determination of key seascape, landscape and spatial elements, features, and values. Aspects considered include:

– Land use and built form.
– Landform, topography, and hydrology
– Vegetation
– Views
– Historical features.
– Coastal edge
– Water column depth and qualities
– Seabed geology and form
– Key habitats, features, and species

A visual analysis was also undertaken to establish:

– The key views
– The Projects viewsheds
– Other visual features within the study area

2.4 Assessment

2.4.1 Landscape character zones

Landscape character considers common landscape zones defined by typical features and characteristics identified during the desktop assessment and site inspection. Defining landscape character zones (LCZs) identifies areas sharing the same homogenous environmental or cultural qualities or pattern such as topography, vegetation, hydrology, land use and settlement, built form scale and character, cultural and recreational characteristics.

This approach has been used to establish the existing landscape character within the study area and to provide a framework for measuring the effects of the Project. This assists in:

– Defining landscape elements that contribute to defining character.
– Defining landscape character attributes
– Identifying landscape value.

The assessment of the existing environment also considers factors which have influenced landscape change in the past and those that are likely to do so in the future. The landscape character zones are defined in Section 6.1.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Landscape value

When defining LCZs, the value attached to the landscape also forms the baseline for which the significance of the assessment is measured. Landscape value looks at designated and undesignated landscapes, and holistically at all the elements such as the environmental, cultural, historical, and visual/sensory elements that form the landscape. The value of the landscape from an international, national, local and community level is considered when applying a landscape value. The following factors are taken into consideration (Natural England, Scottish Natural Heritage and Countryside Council, 2011):

– Landscape quality
– Scenic quality
– Rarity
– Representativeness
– Conservation value
– Recreation value
– Perceptual aspects/qualities
– Associations.

Table 1 Landscape value

Landscape value	Definition
High	Seascape character elements in good or above average condition and/or that make a strong positive contribution to landscape character. May include nationally important features.
Medium	Seascape character elements in reasonably good condition and/or that make an average contribution to the local character, which may include locally important landscape features.
Low	Seascape character elements in below average condition and/or that are not particularly distinctive local features.

2.4.1.1 Seascape Character

Seascape character assessment (SCA) has emerged as a method for assessing, characterising, mapping, and describing seascape character. The SCA follows the well-established, process of Landscape Character Assessment (LCA). This is a process of characterising the seascape that currently exists and classifying character areas and types to be used as a baseline for assessment.

Criteria for assessing the value of the landscape and seascape is defined in Section 6.

2.4.2 Landscape character effects

Assessment of landscape effects deal with the effect of change and development on landscape as a resource. The concern is with how the Project would affect the elements that make up the landscape, the aesthetic and perceptual aspects of the landscape and its distinctive character. The consideration of potential effects on landscape character is determined based on the sensitivity of the existing landscape and the magnitude of change that is likely to occur.

The sensitivity and magnitude of landscape effects address the following specific criteria:

– Sensitivity of landscape to proposed change is judged on a combination of the landscape value and the landscape susceptibility to change from the type of development proposed (refer Table 1 and Table 2). A judgement on the level of sensitivity is made and a rating of high, medium, or low applied.
– The magnitude of change to landscape character is based on the size or scale of change, the geographical extent of effects, and the duration and reversibility of effects (refer Table 3). It also depends on the loss, change or addition of any feature to the existing landscape. It is based on the part of the landscape character zone which is likely to be affected to the greatest extent by the Project.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

An assessment is made on the overall level of significance in relation to the existing conditions (refer to section 0).

Table 2 Landscape susceptibility to change.

Landscape susceptibility	Definition
High susceptibility to change	The type of development proposed could have a detrimental effect on the landscape character, condition, or value. Mitigation measures are unlikely to reduce the effects of the change.
Medium susceptibility to change	Any change caused by the type of development would be unlikely to have a significant adverse effect on the landscape character, condition or value that could not be mitigated.
Low susceptibility to change	Development of this type is unlikely to have an adverse effect on the landscape character, condition, or value. Mitigation measures would be effective in neutralising adverse effects.

Table 3 Magnitude of change criteria (landscape)

Rating	Criteria
High	A substantial/obvious change to the landscape character due to total loss of, or change to, elements, features, or characteristics of the landscape. Would cause a landscape to be permanently changed and its quality diminished.
Medium	Discernible changes in the landscape character due to partial loss of, or change to elements, features, or characteristics of the landscape, however, has potential to be partly mitigated. The change would be out of scale with the landscape character, and at odds with the local pattern and landform and would leave an adverse effect on the landscape character.
Low	Minor loss or alteration to one or more key landscape character elements, features or characteristics, or the introduction of components that may be new but may not be uncharacteristic within the existing landscape character.
Negligible	Almost imperceptible or no change in the landscape character as there is little or no loss of/or change to the elements, features, or characteristics of the landscape.

2.4.3 Viewpoint selection

Assessment of visual effects deals with the effects of change and development on the views available to people and their visual amenity. It assesses how the surroundings of individuals or groups of people may be specifically affected by changes in the context and character of views as a result of the change or loss of existing elements of the landscape and/or the introduction of new elements.

Visual receivers have been considered in terms of the views they are likely to obtain from within the study area including consideration of any key vantage points, such as lookouts, where there is particular interest in the view. Visual receivers are identified based on:

– Proximity of the receivers to the Project, as the most affected visual receivers are anticipated to be located closest to the Project, unless located at an elevated vantage point.
– Type of receiver, as different viewer types would have different perceptions of the change.

Based on the analysis of the existing landscape and visual environment, viewpoint locations were selected for assessment as representative of sensitive visual receiver locations. To best illustrate the likely visual effects of the Project, where appropriate, viewpoint locations chosen for assessment aim to represent a balance of:

– The most sensitive visual receivers
– A range of visual receiver types
– A range of distances from the Project
– A range of view directions towards the Project within the study area.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

2.4.4 Visual assessment

The evaluation of potential effects on visual amenity is based on the sensitivity of the viewpoint (and the visual receiver it represents) to change, and the magnitude of change that is likely to occur. The assessment considers the likely effects of the Project. The level of effects on a view depends on factors such as the extent of visibility, degree of obstruction of existing features, degree of contrast with the existing view, angle of view, duration of view and distance from the Project.

The sensitivity and magnitude of visual effects addresses the following specific criteria:

– The sensitivity of the viewpoint to proposed change considers the importance of the view, its existing scenic qualities, and the presence of other existing man-made elements in the view; type of visual receiver and their likely interest in the view; susceptibility of visual receivers to change, and value attached to views.
– The magnitude of change to views and visual amenity considers the size or scale of change; geographical extent of effects, and duration and reversibility of effects (referTable 5). It also depends on the loss, change or addition of any feature in the field of view of the receiver including an assessment of the level to which the change contrasts with the existing view or expected view of the landscape.

An assessment is made of the overall level of significance in relation to the existing view.

Table 4 Sensitivity criteria (visual)

Rating	Criteria
High	Occupiers of residential properties, at home or going to or from, with long viewing periods, within proximity to the proposed development; Communities that place value upon the landscape and enjoyment of views of their setting.
Medium	Outdoor workers who have a key focus on their work who may also have intermittent views of the study area; Viewers at schools, or similar, when outdoor play and recreation areas are located within proximity but viewing periods are limited; Occupiers of residential properties with long viewing periods, at a distance from or screened from the study area.
Low	Road users in motor vehicles, trains or on transport routes that are passing through or adjacent to the study area and therefore have short term views; Viewers indoor at their place of work, schools or similar.

Table 5 Magnitude of change criteria (visual)

Rating	Criteria
High	A substantial/obvious change to the existing view due to total loss of, or change to, elements, features, or characteristics of the view. Would cause a view to be permanently changed and its quality diminished.
Medium	Discernible changes in the existing view due to partial loss of, or change to elements, features, or characteristics of the view, however, has potential to be partly mitigated. The change would be out of scale with the existing view and would leave an adverse effect on the view.
Low	Minor loss or alteration to one or more key view elements, features or characteristics, or the introduction of components that may be visible but may not be uncharacteristic within the existing view.
Negligible	Almost imperceptible or no change in the view as there is little or no loss of/or change to the elements, features, or characteristics of the view.

2.4.5 Significance of effects

The combination of sensitivity and magnitude determines the significance of the effect on the landscape character or representative viewpoint. Refer to Table 6 for the matrix used to determine the significance of effect.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 6 Significance of effect matrix

Sensitivity	Magnitude of change: High	Medium	Low	Negligible
High	Major (Significant)	Major (Significant)	Moderate (Probably significant)	Minor (Not significant)
Medium	Major (Significant)	Moderate (Probably significant)	Minor (Not significant)	Negligible (Not significant)
Low	Moderate (Probably significant)	Minor (Not significant)	Negligible (Not significant)	Negligible (Not significant)

2.4.6 Panorama and photomontage

Visualisations were conducted by subconsultants OLA of 1270 Fulton Street #3, Brooklyn, New York.

These are Artistic Impressions only and do not meet the LVIA technical photomontage standards as set out in *"The Landscape Institute Advice Note 06/19 Visual Representation of Development Proposals".*

The photographic methodology was non-standard and therefore the visualisations non-compliant with the internationally recognised standard of *LI TGN-06-19 Visual Representation, as specified in the TOR*.

The photo data did not have GPS capability embedded, the focal length was variable, the ground pictures are taken with a Nikon D810 with a Nikon 24-70 Lens. Tripod use is unknown, height above ground is unknown.

The Artistic impressions were conducted using the following methodology from the subcontractor OLA:

"The 3D modelling was carried out using Rhino software. The camera lens length was matched to the model view with the camera view, by matching roads in the model with the road angles in the view. We used Rhino to overlay the photo with the model. However, note that 3D or 2D drawings in Rhino never exactly match what is built or existing."

It should be noted that Rhino is a non-compliant software for producing LVIA technical photomontages.

These artistic impressions are approximate and produced without appropriately accurate geolocation and topography data and therefore should not be relied upon for a LVIA visual impact assessment.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

2.5 Mitigation measures

Mitigation measures were developed in response to the effects identified within Section 6 and Section 0. Potential mitigation measures would typically include:

– Adopting alternative designs or revisions to the basic engineering and architectural design to prevent and/or minimise negative effects.
– Remedial measures such as colour and textural treatment of structural features.
– Compensatory measures such as landscape design to compensate for unavoidable negative effects and to attempt to generate long-term positive effects.

3. Project description

The following section provides a summary of the Project and includes the detail relating to the main visual components that have potential to affect the landscape character and visual amenity of the study area.

3.1 The Project site

The Project site covers approximately 30 acres (12.4 hectares (ha)) of land that is partially vacant and undeveloped on the eastern side of the west peninsula of Grand Cayman. The site has been disturbed by previous activities (including landfill) and consequently it contains no naturally occurring features. In common with large parts of Grand Cayman, the Project site has a ground level height that is only a few metres above sea level as a result of the geology of low-lying limestone and dolostone rocks.

3.2 The Project

The Project is located on the northern edge of George Town in an area that is zoned ‘Heavy Industrial’ (HI). It is bounded to the east and south by other HI land-uses comprising a mixture of vacant lots and small-scale industrial businesses such as marine fitters, metal workers and processing of quarried stone. Areas of hardstanding are interspersed with areas of rough grass and patches of scrub vegetation. Immediately north of the site lies George Town Landfill (GTLF). To the west is an area of mangrove and the Esterly Tibbetts Highway, and to the northeast is the Cayman Islands wastewater treatment plant.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

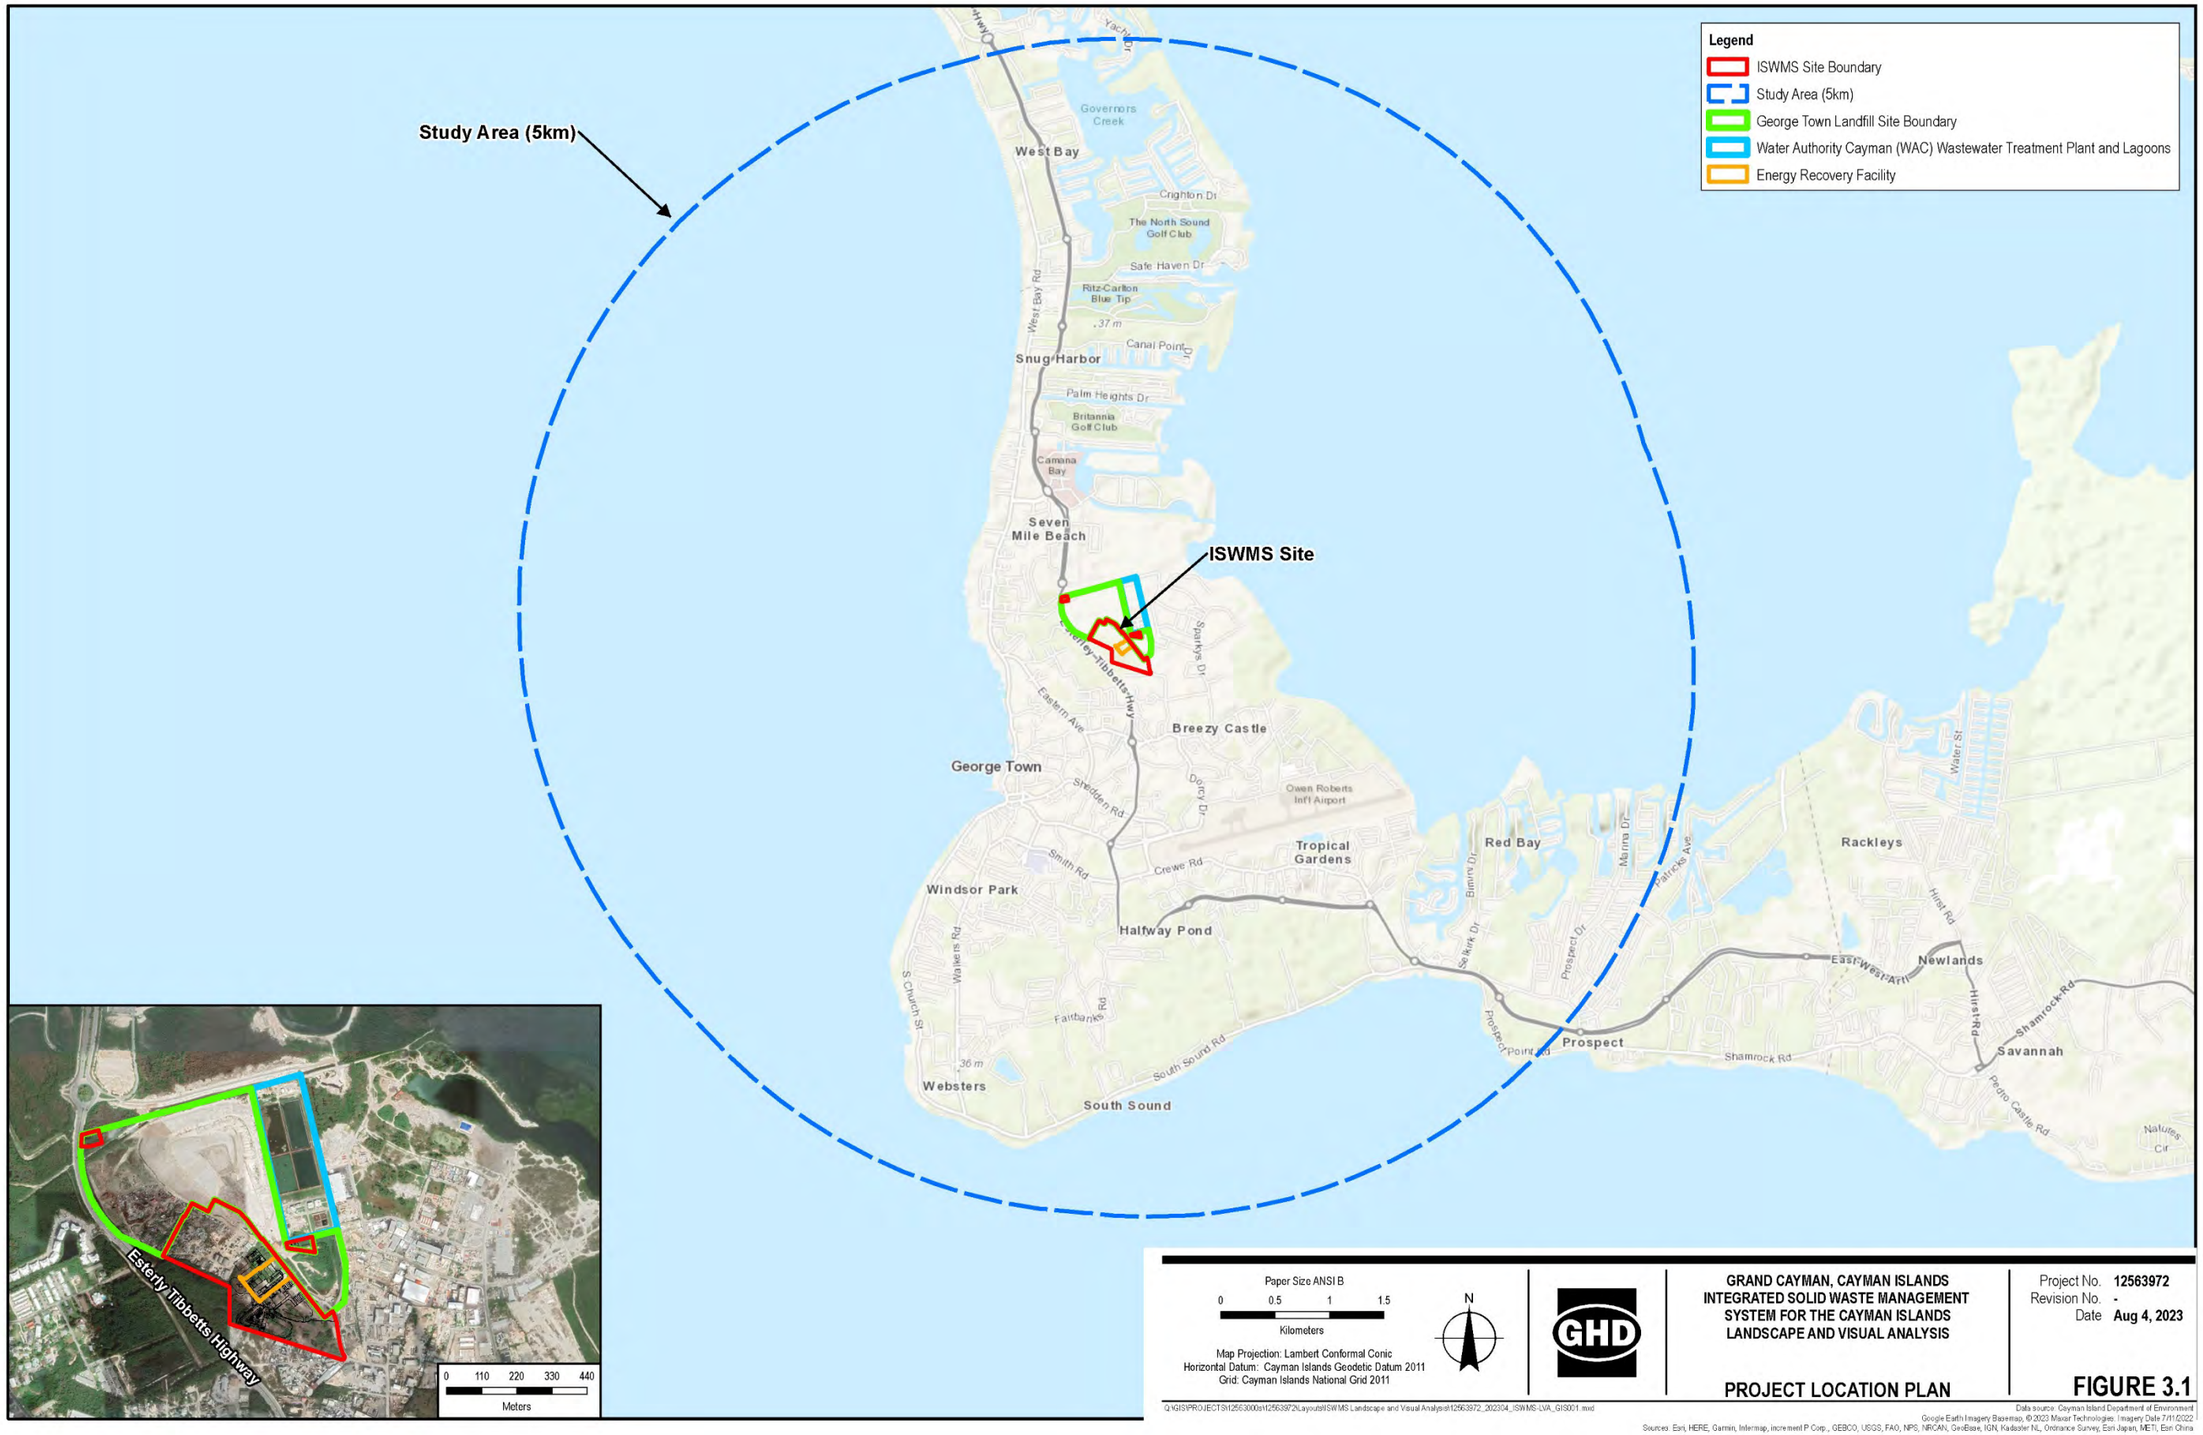

Figure 2 The project site

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

4. Legislation and policy

The following section provides an overview of relevant legislation and policy objectives relevant to landscape and visual considerations within the study area.

4.1 State legislation and framework

Land use planning, including zoning and development control, is governed primarily by local environmental plans (LEPs). LEPs include lists of local heritage items and local heritage precincts and provide controls on development which may affect those items or be located in those precincts. The study area for the project is within the Local Government Area (LGA) of Grand Cayman. The relevant LEPs for this Council area were reviewed for the purpose of preparing this report.

4.1.1 Cayman Islands Constitution Order, 2009

The Cayman Islands Constitution Order of 2009 was developed in order to establish the powers and activities of the legislative, executive, and judicial branches of government, as well as the rights of all citizens. Section 18 of this Constitution provides the basis for the legal protection of the environment, and states the following:

> *Government shall, in all its decisions, have due regard to the need to foster and protect an environment that is not harmful to the health or well-being of present and future generations, while promoting justifiable economic and social development.*
>
> *To this end government should adopt reasonable legislative and other measures to protect the heritage and wildlife and the land and sea biodiversity of the Cayman Islands that –*
>
> *(a) limit pollution and ecological degradation.*
>
> *(b) promote conservation and biodiversity; and*
>
> *(c) secure ecologically sustainable development and use of natural resources.*

4.1.2 Cultural and Natural Heritage Sites

Cultural and Natural Heritage sites are important resources on Grand Cayman. These heritage site resources include both designated features protected by legislation and features of national or local archaeological, historical, or architectural interest. Based on the type and location of the proposed project the studies for the EIA will focus on terrestrial heritage resources within the project study area.

Heritage site resources are identified and/or protected under the following legislation:

– National Conservation Act (2013) – Under Part 3 - Conservation of Land, the Cabinet may designate any area of Crown Land or Cayman waters as a “protected area”.
– National Trust Act (2010) – National Trust for the Cayman Islands (NTCI) ownership or management of specific sites – Allows the NTCI to protect those sites from offences “for actions which could harm Trust property or otherwise contravene the purposes of the Trust.”[2].
– Heritage Register (2010) – Records the Islands’ “natural, historic and cultural resources which are recognised and designated by the Council of the National Trust as being nationally significant and worthy of preservation.”

[2] Bullings, K., Cayman Islands; National Trust for the Cayman Islands. NATIONAL TRUST LAW (2010 Revision). 2010, October 19

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Entries are predominantly historic homes, civic and religious structures. Listing on the Heritage Register does not afford individual sites legal protection.

– Public Lands Act (2020) – Regulates the use of public land in the public interest.

4.2 Local legislation and policy

4.2.1 Planning policy

Planning policy is set out by the Cayman Islands Government Central Planning Authority (CPA) and approved by Parliament. The LVIA will consider planning policy which is relevant to the proposed development as summarised in the Development Plan 1997 (being the plan for zoning and physical development of the Cayman Islands).

Extant policy in the Development Plan 1997 is also presently under review. In November 2018, the CPA published, for consultation, a new draft National Planning Framework. As this new policy emerges, the LVIA will, as appropriate, take cognisance of this evolving, new policy.

Building height restrictions

Height restrictions aren't specified within the Industrial zone; however, it is anticipated that the ERF will exceed the height of the surrounding built form. The Development and Planning Regulations (Development and Planning Act 2021) Regulation 8.2 stipulates *a maximum permitted height of the building shall not exceed:*

- *one hundred and thirty feet* (39.6 m) *or ten storeys, in Hotel/Tourism zone 1:*
- *ninety-one feet* (27.74 m) *or seven storeys, within a General Commercial zone;*
- *sixty-five feet* (19.8 m) *or five storeys or for Hotel/Tourism zone;*
- *forty feet* (12.2 m) *or three storeys in a high-density Residential zone, and the building shall be so designed that no continuous vertical facade or elevation exceeds twenty-five feet or two storeys in height.*

A review of current planning requirements for maximum heights and compliance of the stack of 48.1 m, the ERF boiler house of 37.8 m and ERF waste bunker of 33.4 m will be included in Chapter 4.

Scenic Shoreline

The Development and Planning Regulations (Development and Planning Act 2021) Regulation 20 - Scenic shoreline, stipulates:

– *It is the duty of the Authority to ensure that the open character of scenic shoreline land is preserved, in particular that of the beaches, and also to safeguard the public's right to use the beaches and to gain access to them through public rights of way.*

4.2.2 Waste management policy

Waste management policy for the Cayman Islands is set out in the following key documents:

National Solid Waste Management Policy for the Cayman Islands (August 2015); and

National Solid Waste Management Strategy for Cayman Islands (2016); and the associated Integrated Solid Waste Management System for the Cayman Islands – Outline Business Case (2016).

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

5. Existing landscape and visual environment

The following section provides a summary of the existing landscape and visual environment of the study area.

5.1.1 Land use and built form

The proposed site is situated within an area of mixed low-density residential neighbourhoods with single-family homes and high-density commercial areas with multi-story buildings. The green spaces within the area are predominantly mangrove forest and woodlands. The immediate surroundings of the proposed site are zoned for industrial or commercial use and feature warehouses, factories, and storage yards.

The landscape of George Town Centre is predominantly characterised by high-density commercial development, including tall buildings, while West Bay Road is the main tourist drive through the tourist district. The ruins of an 18th-century fort and historical architecture, such as the George Town Library and Town Hall, add to the town centre's unique character. Contemporary Caymanian architecture is also present, such as The Harquail Theatre and The Paseo in Camana Bay.

As one moves further away from the city centre, the built form becomes less dense, with lower-rise buildings and more open green spaces. The periphery of the study area is dominated by automotive repair, bodyworks shops and concrete batching plants.

The human programming of the area caters towards tourists and their use of the linear beaches bordering the extent of the study area. Access to recreational green spaces is limited, with small pockets of accessible green areas such as Airport Park and Dart family park. Other facilities within the area include the Truman Bodden Sports Complex, the University of the Cayman Islands, and Grand Cayman's Hospital.

5.1.2 Topography and hydrology

The study area is defined by its unique topography and hydrology. A large bay and beach on the West side punctuates the flat terrain. The Ironshore geological formation primarily characterises the area, and the most significant feature is the North Sound Lagoon, located on the eastern side of the study area. It is a reef-protected lagoon covering approximately 34.75 square miles (90 square km), of which the study area covers about half. The lagoons foreshore is characterised by shallow coral reefs and pockets of established mangrove vegetation.

The topography in the northeast regions of the study area has undergone significant modifications due to the island's evolving landscape and changing land use patterns. Canals and channels have been cut through the island to convert mangrove areas to residential waterfront properties.

5.1.3 Vegetation

The study area's vegetation on the west side is comprises a mix of modified and remnant habitats. The flat topography is scattered with sparse clusters of palm trees amongst the existing mixed species and mangrove vegetation. With single palm trees and other tree species used to line the tourist drive along West Bay Road.

The study area's eastern and southern sides are dominated by remnant low-lying coastal mangroves and sedge vegetation, which serve a dual purpose of tidal and flood mitigation while providing essential habitat for local fauna. Palm trees can be spotted growing amidst the mature mangrove vegetation.

The North Sound lagoon on the zone's eastern side is the island's most significant protected bay. Its fringing mangroves, and seagrass beds serve as critical breeding and nursery habitats for marine fauna. The underwater topography beyond the fringing reef of North Sound Lagoon is characterised by two well-developed spur-and-groove terraces: a shallow terrace reaching a depth of nine meters and a deeper one at fifteen meters. The vegetation and topography of the study area create a unique and valuable ecosystem that needs to be protected and conserved.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

5.1.4 Key visual features

Based on the desktop review and site inspection, the key visual features in the study area were identified as:

– Views along the coast from West Bay Road's linear tourist drive are a significant visual feature of the district.
– The observation tower at Camana Bay is a striking visual landmark that attracts many tourists and provides elevated views out across the island and coast.
– The ruins of the 18th-century fort on Harbour Drive and Fort Street add historical interest to the streetscape.
– The mix of historic and contemporary architecture includes the George Town Library, Town Hall, The Harquail Theatre, and The Paseo in Camana Bay.
– Caymanian style of zinc-roofed, pastel-painted, wood-boarded cabins with louvred shutters and fretworked porch.
– The new developments in the northern zone, featuring colonial-style masonry buildings and other residential communities, add to the visual landscape.
– The Truman Bodden Sports Complex, The University of the Cayman Islands, Grand Cayman's Hospital, the Government Administration Building, and the National Art Gallery add modern architectural elements to the landscape.
– The unusual high point of George Town land fill is also a significant visual feature of the local area.

DRAFT

6. Landscape and seascape character assessment

The study area has been classified into five LCZs and SCZs.

These LCZs and SCZs have different associated sensitivities to potential changes as a result of the Project. The sensitivities are discussed below and have informed the assessment. Figure 5, and are as follows:

LCZ1: Tourism foreshore and George Town centre

LCZ2: Industrial, waste and airport

LCZ3: Residential settlement

SCZ4: Mangroves and recreation

SCZ5: Caribbean Sea and North Sound Lagoon

Summary of LCZ 1

LCZ1 is a designated tourism industry zone with a concentration of tourism activities along the western coastal area. The site's topography is relatively flat, with a foreshore characterised by shallow coral reefs and beaches lined with palm trees and other tree species which provide a scenic backdrop for the linear tourist drive along West Bay Road. The streets' edges feature a mix of hotel buildings with direct beach access interspersed with popular tourist destinations such as eateries, fishing spots, cabana bars, and restaurants, which buffer the land and sea with the cruise ship docking points located just offshore.

George Town Centre, the bustling hub of Grand Cayman Island, is steeped in history, and remnants of the island's past are visible throughout. The Cayman Islands National Museum provides a glimpse into the island's rich heritage, with the building being one of the few surviving nineteenth-century structures on the Islands. Old launching ramp sites of the schooners cut into the bedrock around George Town still exist, while throughout the town centre, a mix of contemporary and historical architecture can be seen. The Paseo in Camana Bay offers a new urbanism development style featuring modern architecture and is home to popular tourist attractions.

Key characteristics of LCZ1 include the following:

– West Bay Road is the main tourist drive and runs through the tourist district.
– The observation tower is a popular tourist attraction in Camana Bay.
– George Town cruise port is a vital link for docking cruise ships.
– Ruins of an 18th-century fort on the corner of Harbour Drive and Fort Street stand as a testament to the island's past.
– The city's historical architecture includes buildings such as the George Town Library and Town Hall.
– Contemporary Caymanian architecture includes buildings such as The Harquail Theatre, the Government Administration Building, and The Paseo in Camana Bay.

Values associated with LCZ1 include:

– The zone is designated for tourism industry with a concentration of tourist activities along the western coastal area, which features beaches and palm trees that provide a backdrop for the linear tourist drive along West Bay Road.
– The George Town Centre is steeped in history, with remnants of the island's past visible throughout. The city features historical architecture, such as the ruins of an 18th-century fort, the George Town Library built-in 1939, and the Peace Memorial Town Hall built-in 1919.
– The Harquail Theatre and The Paseo in Camana Bay offer a new urbanism development style, featuring modern architecture.
– The area is home to popular tourist destinations such as eateries, fishing spots, cabana bars, and restaurants that offer a glimpse into the Caymanian culture.
– The George Town cruise port is a vital link for docking cruise ships, and the Cayman Islands National Museum provides a glimpse into the island's rich heritage, making it a hub for connectivity and cultural exchange.

Character elements make a strong contribution to the local character, including locally important landscape features. LCZ1 therefore has a **High** landscape value.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 7 LCZ1 assessment

Landscape character zone 1: Tourism foreshore and George Town centre	
Anticipated change to landscape character	The Project site is not in LCZ1. The anticipated change to the landscape character of LCZ1 would be indirect and relate to the modifications of the landscape character in LCZ2. The more prominent elements include a 48.1-metre-high ventilation stack and an enclosed processing facility at heights of between 37.8 m for the boiler house and 33.4 m for the waste bunker. These are likely to be the tallest and, therefore, the most visible components of the Project, but at and minimum distance of approximately one kilometre from the Project sight, the building height will be mitigated by the existing landscape, with the top of the stack being the most prominent element viewable at various locations throughout LCZ1.
Susceptibility to change	LCZ1 has a **Medium** susceptibility to change. The character is of high value to the tourism industry, which is a large part of the islands economy, any change caused by the type of development would be unlikely to have a significant adverse effect on the landscape character, condition or value that could not be mitigated.
Sensitivity to change	The sensitivity of a landscape is judged on a combination of the landscape value and the landscape's susceptibility to change from the type of proposed development. The sensitivity would be **Medium**, as the landscape value is High and the susceptibility to change is Medium.
Magnitude of change	The magnitude of change would be **Negligible**. There is no change in the landscape character as there is little or no change to the elements, features, or characteristics of the landscape.
Significance of effect	The significance of effect would be **Negligible**, as the sensitivity is **Medium** and the magnitude is **Negligible**.

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

6.1.2 Landscape character zone 2: Industrial, waste and airport

The key features of LCZ2 are described below and illustrated in Photo 6.7 to Photo 6.12. The LCZ2 assessment is outlined in Table 8.

Photo 6.7 Seymour Road looking toward Supermix in a southwest direction

Photo 6.8 Sleepy Hollow drive looking north

Photo 6.9 Seymour Road looking northwest

Photo 6.10 Taken at Central Laundry looking west towards proposal site which is visible in background

Photo 6.11 Sparkys Drive looking west

Photo 6.12 View of airport taken at Crewe Road and Desmond Drive

Summary of LCZ 2

LCZ2 is a designated area for industrial and waste industries as well as the Owen Roberts International airport located primarily to the east and south of the Project site. The zone's flat topography is characterised by industrial buildings and warehouses, which vary from automotive to construction. Two of the island's authorities are located within this zone. While there are some smaller undeveloped green sites. Owen Roberts International Airport is about 1.86 miles (3 km) southeast of the George Town centre on the southern side of North Sound Lagoon. The roads in the zone are a mix of sealed and unsealed roads, with some space undergoing redevelopment for

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

industrial businesses. Overall, the area is dominated by large industrial buildings and warehouses, creating an industrial landscape.

Key characteristics of LCZ2 include the following:

– Automotive repair and bodyworks shops along with concrete batching plants form a considerable proportion of agency within the zone.
– Water Authority for the island and the Cayman Islands Aviation Authority are located here.
– Comprises sparse inclusions of mixed species vegetation.

Values associated with LCZ2 include:

– LCZ2 plays a vital role in the local economy as a hub for various industries, including automotive shops, cement and concrete refineries, and waste management.
– The zone houses essential infrastructure like the Water Authority and Cayman Islands Aviation Authority, which are crucial for supporting the island's population and industries.
– The industrial businesses within LCZ2 provide job opportunities for the local community and contribute to the island's economic growth.
– Despite being an industrial zone, LCZ2 has some undeveloped green sites that provide ecological benefits like carbon sequestration and habitat for wildlife.
– While not explicitly mentioned in the statement, the history and cultural significance of industrial activities on the island can be considered a value associated with LCZ2.

LCZ2 has a **Low** landscape value rating as the landscape character elements are in below-average condition and are not particularly distinctive local features.

Table 8 LCZ2 assessment

Landscape character zone 2: Industrial, Waste and airport	
Anticipated change to landscape character	The Project is located within LCZ2, and while it fits within the function of the designated zone, the height of the facility and its components will be almost three times higher than any other building within this zone, the ventilation stack being the tallest structure on the island.
Susceptibility to change	The Project is located within the industrial zone and on land which has been disturbed by previous waste management activities. Consequently, there are no sensitive landscape elements which could be significantly affected by the construction or operation of the proposed development it therefore has a **Low** susceptibility to change based on any change caused by the type of development would be unlikely to have a significant adverse effect on the landscape character, condition or value that could not be mitigated.
Sensitivity to change	The sensitivity of a landscape is judged on a combination of the landscape value and the landscape's susceptibility to change from the type of proposed development. The sensitivity would be **Low**, as the landscape value is Low and the susceptibility to change is Low.
Magnitude of change	Due to the height of the prosed design with the associated stack being the highest component and therefore being the highest point on the island the magnitude of change would be **High** as the type of development proposed could have a detrimental effect on the landscape character, condition, or value. Mitigation measures are unlikely to reduce the effects of the change due to the height of the associated buildings (37.8 m and 33.4 m) and ventilation stack (48.1 m).
Significance of effects	The significance of effects would be **Moderate**, as the sensitivity is Low, and the magnitude is High.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

6.1.3 Landscape character zone 3: Residential settlement

The key features of LCZ3 are described below and illustrated in Photo 6.13 to Photo 6.18. The assessment is outlined in Table 9 .

Photo 6.15 North side of Keturah Street looking south.

Photo 6.16 East side of Sorrel Drive looking south west.

Photo 6.14 South side of Selkirk Drive looking west.

Photo 6.17 South side of Crewe Road looking north.

Photo 6.13 East side of Abbey Way looking west.

Photo 6.18 West side of Canal Lane looking north east.

Summary of LCZ3

LCZ3 is a mix of low to medium-height buildings and single-family homes - each showcasing unique Caymanian-style architecture from the 19th century. Modern homes have replaced wood with masonry while incorporating a pastel colour scheme. Picturesque palm trees are scattered throughout, sometimes in clusters and occasionally alone. Residential areas are sometimes uniform, while others have winding roads and cul-de-sacs. The northern portion of the zone has new residential developments and numerous community facilities and churches. Large green spaces are scattered throughout the zone.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Key characteristics of LCZ3 include the following:

– Unique Caymanian style of zinc-roofed, pastel-painted, wood-boarded cabins with louvred shutters and fretworked porch.
– New developments underway at the northern portion of the zone, featuring colonial-style masonry buildings and gated communities.
– Location of the Truman Bodden Sports Complex, the leading sports arena of the island.
– Other facilities include the University of the Cayman Islands, Grand Cayman's Hospital, and the National Art Gallery.
– Numerous churches represent the Cayman Islands' religious context.

Values associated with LCZ3 include:

– Unique blend of traditional and contemporary Caymanian architecture, including zinc-roofed, pastel-painted, wood-boarded cabins with louvred shutters and fretworked porches, and masonry buildings with pastel colour schemes.
– The presence of palm trees adds to the residential Zone's picturesque allure
– Residential facilities are abundant, including the Truman Bodden Sports Complex, The National Art Gallery and numerous churches that represent the religious context of the Cayman Islands.
– Educational and Healthcare Values: Several schools such as the University of the Cayman Islands, St. Ignatius High School, and Cayman Prep & High School, and The Grand Cayman's Hospital are located in the area.

As the environmental, recreational, and educational landscape values make a strong contribution to the local character, LCZ3 has a **High** landscape value rating.

Table 9 LCZ3 assessment

Landscape character zone 3: Residential settlement	
Anticipated change to landscape character	The Project is situated beyond LCZ3, and the expected effect on the landscape will vary based on how close residential areas are to it. The ventilation stack is the most noticeable feature, and any efforts to reduce its effect will have a minor effect due to its height. Depending on their location, residents may be able to see the top of the stack from their homes.
Susceptibility to change	The susceptibility to change for LCZ3 is **Medium**, this is due to the height of the ventilation stack exceeding that of any vegetation found in this or any other LCZ. The change caused by the proposed development would be likely to have an adverse effect on the landscape character, condition, or value, that could not be mitigated.
Sensitivity to change	The sensitivity of a landscape is judged on a combination of the landscape value and the landscape's susceptibility to change from the type of proposed development. The sensitivity would be **High**, as the landscape value is High and the susceptibility to change is Moderate.
Magnitude of change	Based on the height of the Project's buildings and ventilation stack, the magnitude of change for LCZ3 would be **Negligible.** With discernible changes in the landscape character due to partial loss of, or change to elements, features, or characteristics of the landscape, however, has potential to be partly mitigated by the current vegetation that would help obscure these elements of the Project from a distance. The change would be out of scale with the landscape character, and at odds with the local pattern and landform and would leave an adverse effect on the landscape character. Based on the Project being located in LCZ2, there would be no change to the landscape character of LCZ3. Therefore, the magnitude of change would be **Negligible**.
Significance of effect	The significance of effect would be **Minor**, as the Project is not in this landscape character zone.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

6.1.4 Seascape character zone 4: Mangroves and recreation

The key features of LCZ 4 are described below and illustrated in Photo 6.19 to Photo 6.22. The SCZ4 assessment is outlined in Table 10.

Photo 6.20 North Sound Gated Community looking east

Photo 6.21 Pinehurst Road Looking east

Photo 6.19 North of Blue Lagoon Drive

Photo 6.22 East side of Safehaven Drive looking east

Summary of SCZ4

SCZ4 is defined by the remnant low-lying coastal mangroves and sedge vegetation dominating the study area's eastern and southern sides. These areas serve a dual purpose of tidal and flood mitigation while providing essential habitat for local fauna. Palm trees can be spotted growing amidst the mature mangrove vegetation. The vegetation has undergone modifications as the island has evolved, and the agency across the landscape has changed. The eastern areas have undergone significant changes, with channels and canals being cut through through the island to convert mangrove areas to residential waterfront properties.

The recreation aspects of this zone are characterised by heavily modified landscapes that serve as golf courses set on the borders of new residential developments set on a canal network, with all other recreational agencies taking place on the beach fronts of the island.

Key characteristics of SCZ4 include the following:

– Small pockets of public green areas, such as Airport Park and Dart family park.
– The public recreational agency taking place is on the beach fronts of the island.
– Private (Golf) recreational activities are undertaken in the golf courses.
– Vegetation has undergone modifications.

Values associated with SCZ4 include:

– The unique and important role of the remnant low-lying coastal mangroves and sedge vegetation in tidal and flood mitigation, as well as their essential habitat for local fauna.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

– The presence of palm trees growing within the mature mangrove vegetation, adding to the area's biodiversity and visual appeal.
– The history of modifications and changes to the landscape as the island has evolved and the agency across the landscape has changed.
– The blending of recreation aspects with heavily modified landscapes such as golf courses, which are still in harmony with the natural surroundings.
– The existence of small accessible green spaces such as Airport Park and Dart family park, providing pockets of nature for public enjoyment.
– The prominence of beach fronts as the main recreational area on the island.

As the ecological and cultural landscape values make a strong contribution to the local character and overall character of Grand Cayman, SCZ4 has a **High** landscape value rating.

Table 10 SCZ 4 assessment

Landscape character zone 4: Mangroves and recreation	
Anticipated change to landscape character	The Project is not located within SCZ4. The approximate distance from the Project is a minimum of two kilometres. At this distance, the anticipated change to view would be negligible; this is due to the height of the stack that would be visible but due to the distance, it would appear blurry and distant, the existing vegetation and buildings that occur between the various locations throughout SCZ4 would also mitigate any significant change to the over character immediately discernible within the zone.
Susceptibility to change	With the Project site being approximately at a minimum two kilometres away in combination with the height of the Project from this distance, the susceptibility of change would be **Low** as the development of this type is unlikely to have an adverse effect on the landscape character, condition, or value. Mitigation measures would be effective in neutralising adverse effects.
Sensitivity to change	The sensitivity of a landscape is judged on a combination of the landscape value and the landscape's susceptibility to change from the type of proposed development. The sensitivity would be **Medium**, as the landscape value is **High** and the susceptibility to change is **Low**.
Magnitude of change	As the Project site not located within this zone, the magnitude of change would be **Negligible**; this is because there is almost imperceptible or no change in the landscape character as there is little or no loss of/or change to the elements, features, or characteristics of the landscape.
Significance of effect	The significance of effect would be **Negligible**, as the sensitivity is Medium and the magnitude is Negligible.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

6.1.5 Seascape character zone 5: Caribbean Sea and North Sound Lagoon

The key features of SCZ 5 are described below and illustrated in Photo 6.23 to Photo 6.26. The SCZ5 assessment is outlined in Table 11.

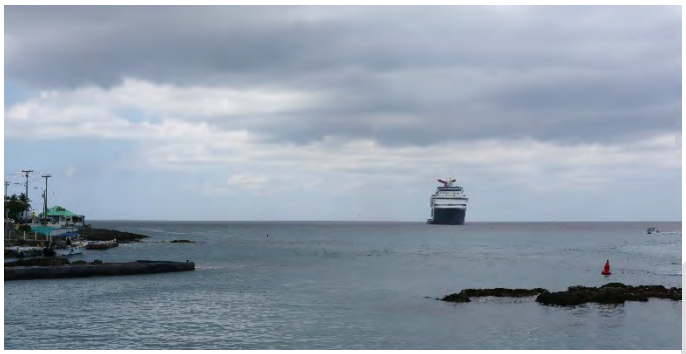

Photo 6.23 View from shore toward cruise ship docking point in the Caribbean Sea

Photo 6.24 View from Governors beach out into Caribbean Sea

Photo 6.25 Coast of Blue Lagoon Drive looking northeast into North Sound Lagoon

Photo 6.26 Sorrel Drive looking east into North Sound Lagoon

Summary of SCZ 5

The Seascape Character Zone 5 (SCZ 5) consists of two distinct seascapes that encircle the project site on its eastern and western sides.

Contrasting the eastern seascape is the western seascape, a popular tourist destination catering to the needs of tourists and residents. The deeper sea sections serve as multiple anchor points for cruise ships that are a significant part of the economy of Grand Cayman. This seascape drives the beach topology that the hotels and tourist attractions rely on and creates the buffer zone between land and sea. Key characteristics of SCZ5 include the following:

– 60% of the North Sound Lagoon is covered by well-developed beds of *Thallassia testudinum* (Turtle Grass).
– The North Sound lagoon (eastern side) is a semi-enclosed, shallow lagoon spanning 85 km^2 and historically surrounded by mangrove swamps and fringed by an exposed acroporidae reef.
– Designated onshore fishing spaces, coral reefs, and sunken shipwrecks for recreational snorkelling and diving.
– The deeper sea sections of the Western seascape serve as anchor points for cruise ships, a significant part of the Grand Cayman economy.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Values associated with SCZ5 include:

– Ecological importance: The North Sound lagoon serves as critical breeding and nursery habitat for marine fauna, and the fringing mangroves and seagrass beds are vital for the ecosystem.
– Recreational opportunities: The western seascape offers recreational activities such as snorkelling, diving, and onshore fishing.
– Economic significance: The western seascape is a popular tourist destination and a significant source of income for the island through cruise ships and hotel establishments.
– Biodiversity: The North Sound lagoon is surrounded by mangrove swamps and an exposed acroporidae fringing reef, providing a diverse range of habitats for marine life.
– Underwater topography: The North Sound lagoon has two well-developed spur-and-groove terraces with varying depths, offering unique diving experiences.

Due to the ecological importance, recreational opportunities, and economic significance of SCZ5 combined with landscape character elements that are in good or above average condition, SCZ5 has a **High** landscape value rating.

Table 11 SCZ5 assessment

Seascape character zone 5: Caribbean Sea and North sound lagoon	
Anticipated change to seascape character	The Project is located outside of SCZ5, with the anticipated change to the seascape character being negligible. Although the top of the stack is anticipated to be viewable at varying locations throughout the zone and varying distances, the Project's site and development would have little effect on the landscape character.
Susceptibility to change	The height of the Project's ventilation stack in SCZ5 is the main contributing factor to the classification; the ventilation stack would unlikely be mitigated through vegetation planting; therefore, SCZ5 has a susceptible to a change rating of **High.** This is because although the top of the stack may be viewable at various locations throughout the zone, any change caused by the type of development would be unlikely to have a significant adverse effect on the seascape character, condition or value that could not be mitigated.
Sensitivity to change	The sensitivity of a seascape is judged on a combination of the landscape value and the landscape's susceptibility to change from the type of proposed development. The sensitivity would be **High,** as the seascape value is **High** and the susceptibility to change is **High**.
Magnitude of change	As the Project is not located within this zone, the magnitude of change would be **Negligible**; this is because there is almost imperceptible or no change in the landscape character as there is little or no loss to change to the elements, features, or characteristics of the seascape.
Significance of effect	The significance of effect would be **Minor**, as the sensitivity is high and the magnitude is negligible.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

7. Visual consideration assessment

Based on the existing environment analysis, sensitive visual receivers were identified, and viewpoint locations selected for assessment.

Regarding potential receptors, consideration of the nature of the Project and the context within which it will be located (i.e., within an area that is zoned 'Heavy Industrial') has led to the judgement that receptors who may have an increased propensity to experience significant effects are those receptor groups assessed as being of a high or medium sensitivity to change.

Sensitive visual receivers within the Project viewshed include the following:

- Residents in dwellings with views to the Project
- Road users along the Esterly Tibbetts highway, including visitors exiting the National Gallery and the Harquail Cultural Centre
- Local road users of West Bay Road
- Nearby workers from the industrial zone
- Tourists/visitors to outdoor attractions
- People undertaking recreational activities where the focus of the activity involves an appreciation of the landscape or where it is likely that their surroundings have some influence upon their enjoyment (e.g., angling and golfing)
- People travelling through the landscape on roads or at sea.

7.1 Viewpoint locations

The following section provides a visual consideration assessment of the Project from the following selected representative viewpoint locations as shown in Viewpoints have been selected to appropriately represent the most sensitive visual receivers who are in close proximity to the site, may have prolonged views to the Project or are in LCZs of high value.

Refer to 7.1.1 to 7.3 for an assessment of the visual effect for each viewpoint location.

Viewpoints have been selected to appropriately represent the most sensitive visual receivers who are in close proximity to the site, may have prolonged views to the Project or are in LCZs of high value.

Table 12 Viewpoint locations

Viewpoint	Location	Description
Viewpoint 1: National Gallery of the Cayman Islands	National Galley of the Caymans Island	National Galley of the Caymans Island - entry drive intersection with Esterly Tibbetts Highway, looking towards GTLF

Viewpoint location 7: Cruise liner	Cruise Liner anchored off Seven Mile Beach	Located approximately 700 meters off the coast of Seven Mile Beach
Viewpoint Location 8: North sound lagoon	Boat located in the North sound lagoon	Located approximately one mile (1.5 km) off the foreshore of the lagoon.

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

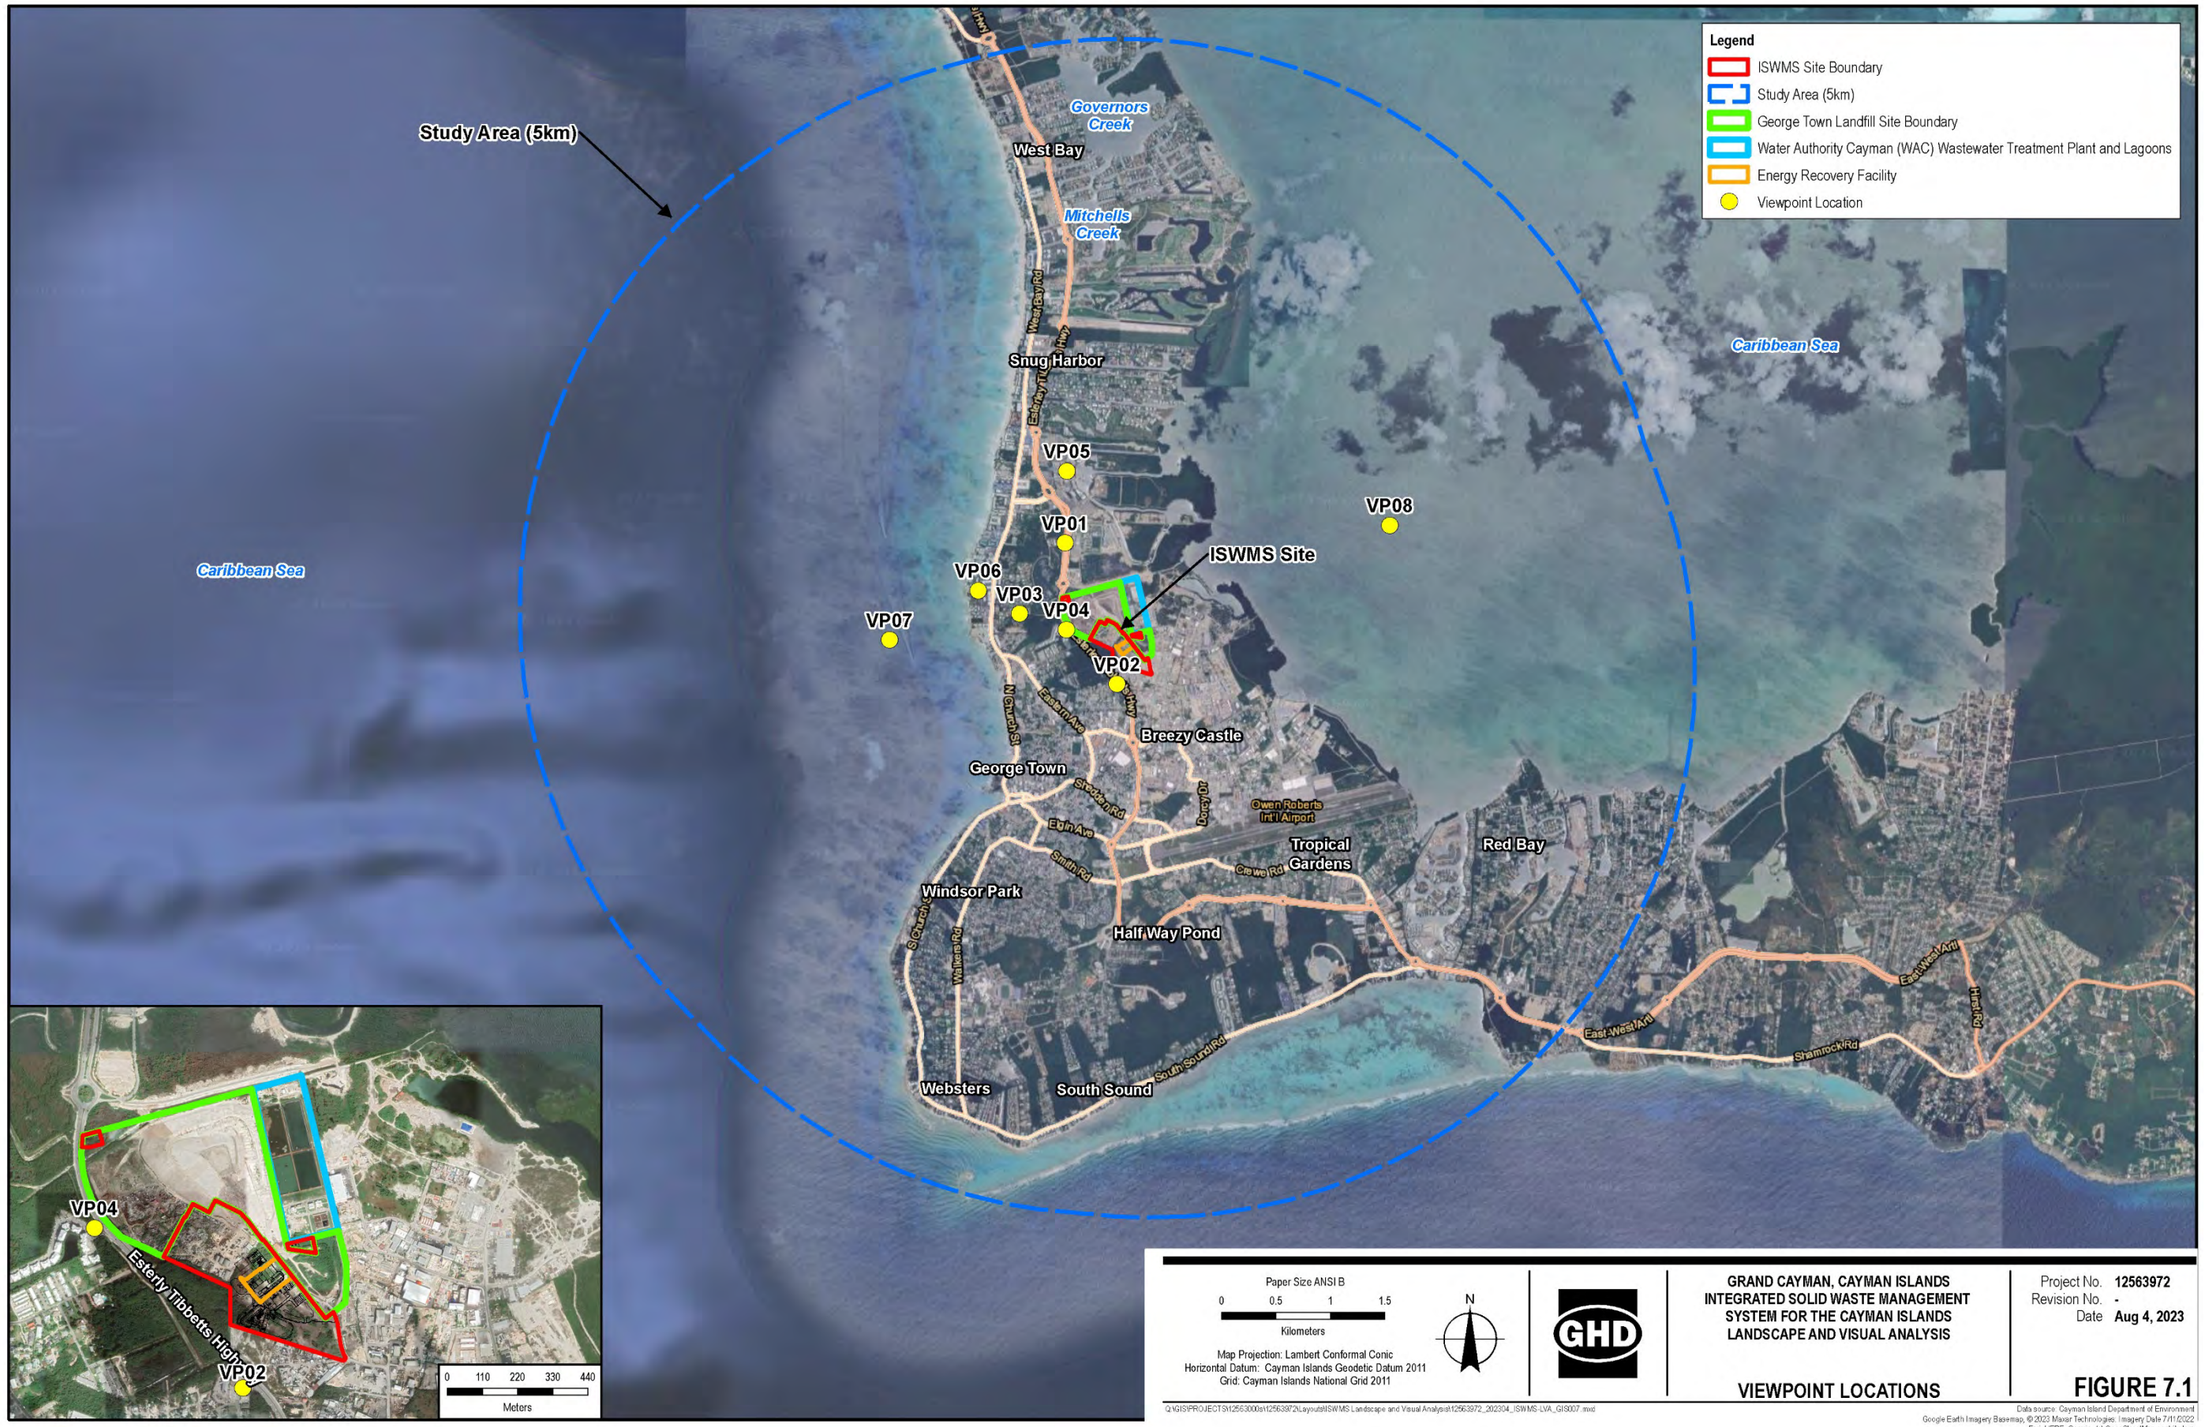

Figure 6 Viewpoint location map

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

7.1.1 Viewpoint 1: National Gallery of the Cayman Islands

VP01 is located at National Galley of the Caymans Island - entry drive intersection with Esterly Tibbetts Highway, looking in a south-eastern direction towards the Project Site. The assessment for VP01 is discussed in Table 13 VP01 assessment. The existing view is illustrated in Photo 7.1 and artistic impressions illustrating the Project design are shown in Photo 7.2.

Photo 7.1 Viewpoint 1: National Galley of the Caymans Island - entry drive intersection - existing view

Photo 7.2 Viewpoint 1: National Galley of the Caymans Island - entry drive intersection – Annotated after construction.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 13 VP01 assessment

Criteria	Comments
Location and view direction	Location (MGA Zone 55); 19.315997, -81.377728 Elevation: VP01 is situated 1,640 feet (500 m) from the Project and is facing in a southeast direction. This viewpoint is representative of views experienced by vehicles along Esterly Tibbetts Highway, as well as visitors to the National Gallery of the Cayman Islands, the users of the Cayman International school along with the users and visitors of the Harquail Theatre, FJ Harquail Cultural Centre.
Description of existing view	The foreground features a clearly defined, raised road division constructed from cement and stone retaining walls and flanked by the Esterly Tibbetts Highway on either side. A series of streetlights occasion the division. In the mid-ground of the image, there is an abundance of vegetation at varying heights. On the far-left side of the composition, several buildings can be seen, providing a sense of urbanity to the landscape. A partially obstructed glimpse of the Project site can be seen through the vegetation in the mid-range of the image. While on the right-hand side of the image, there is a varied and layered composition of mixed vegetation mirrored on the project's peripheral border. At the road edge, beyond the highway, the dense vegetation of shrubs and trees partially screens a construction site and crane in the centre of the background.
Anticipated change to view	In the centre background where the vegetation and tree line meet, a series of large industrial buildings and ventilation stack will be visible. The buildings are visually located behind the existing vegetation line and would be partially obscured from view with the stack being the most visible from this location. Plumes of white steam and gas would be exhausted from the stack during operation, which would make it more visible.
Sensitivity to change	The sensitivity to change is **Low**, as road users in motor vehicles, trains or on transport routes that are passing through or adjacent to the study area and therefore have short term views; Viewers indoor at their place of work, schools or similar.
Magnitude of change	The magnitude of change would be **Medium**, as there would be discernible changes in the existing view due to partial loss of, or change to elements, features, or characteristics of the view, however, has potential to be partly mitigated. The change would be out of scale with the existing view and would leave an adverse effect on the view.
Significance of effect	The significance of effect will be **Minor,** as sensitivity to change is low and magnitude of change is medium.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

7.1.2 Viewpoint 2: United Pentecostal Church

VP02 is located at the northern point of Woodlake Drive in the United Pentecostal Church. The baseline and assessment for VP02 is discussed in Table 7.3 VP02 visual consideration assessment. The existing view is illustrated in Photo 7.3 and artistic impressions illustrating the Project design are shown in Photo ***7.4***.

Photo 7.3 ***Viewpoint 2 existing view***

Photo 7.4 ***Artistic Impression showing the Project from viewpoint location 2***

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 14 VP02 assessment

Criteria	Comments
Location and view direction	Location (MGA Zone 55); 460784.279 E, 2134528.682 N. Note elevation data not provided. VP02 is situated approximately 328 feet (100 m) from the Project and is facing in a northwest direction. This viewpoint is representative of views experienced by residents on Woodlake Drive and the users of the United Pentecostal church.
Description of existing view	The middle-foreground view is defined by the light-coloured concrete car park of the church. The church building can be seen in the far left of the image and is rendered in yellow and white colours. There are two white pillars supporting the roof of the covered entrance, with a minibus parked underneath. The car park is demarked by a low rectangular hedge, creating a low visual barrier to the property boundary and partially screening the Esterly Tibbetts highway beyond. The hedge runs in a linear direction through the mid-range of the view, making a vanishing point to the left of the image; the hedge is occasioned with small rectangular rises that have been trimmed into the hedge's shape, the largest of which can be seen in the centre of the image, of which a streetlight is situated to the left. Behind, runs Esterly Tibbetts Highway and associated chain-link fence, which has vegetation growing through in points. It follows the same linear direction as the hedge but stands taller, adding another layer of visual barrier to the landscape beyond the boundary. Behind the chain-link fence, the tops of mature vegetation can be seen, with the project site visible over this and creating the composition's horizon line. Tall vertical infrastructure creates visual clutter in the mid-ground across the view from left to right, with two utility poles, transmission lines and the lamppost extending above the horizon line. The background consists of tree canopies, filtered views through to the land fill mound of the GTLF and expansive views to the sky.
Anticipated change to view	In the centre background, a series of large industrial ERF buildings and a ventilation stack will be visible. The facilities are visually located behind the existing vegetation line. The lower level of the ERF building will be partially obscured from view by vegetation, however the upper half will be visible above the horizon line, but below the height of the utility pole, transmission lines and church roof, when viewed from this viewpoint.
Sensitivity to change	The sensitivity to change would be **High** as the occupiers of residential properties, users of the car park and church goers would have direct and prolonged views of the project.
Magnitude of change	The magnitude of change would be **High** as a substantial change to the existing view would be undertaken, which would cause the view to be permanently changed and its quality diminished.
Significance of effect	The significance of effect will be **Major** as sensitivity to change is High and magnitude of change is High.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

7.1.3 Viewpoint 3: Residential properties on Marbel Drive Grand Cayman

VP03 is located on Marbel Drive. The assessment for VP03 is discussed in Table 7.4. The existing view is illustrated in Photo 7.5 and artistic impression illustrating the Project design are shown in Photo 7.6.

Photo 7.5 Viewpoint 3: Residential properties on Marbel Drive - existing view

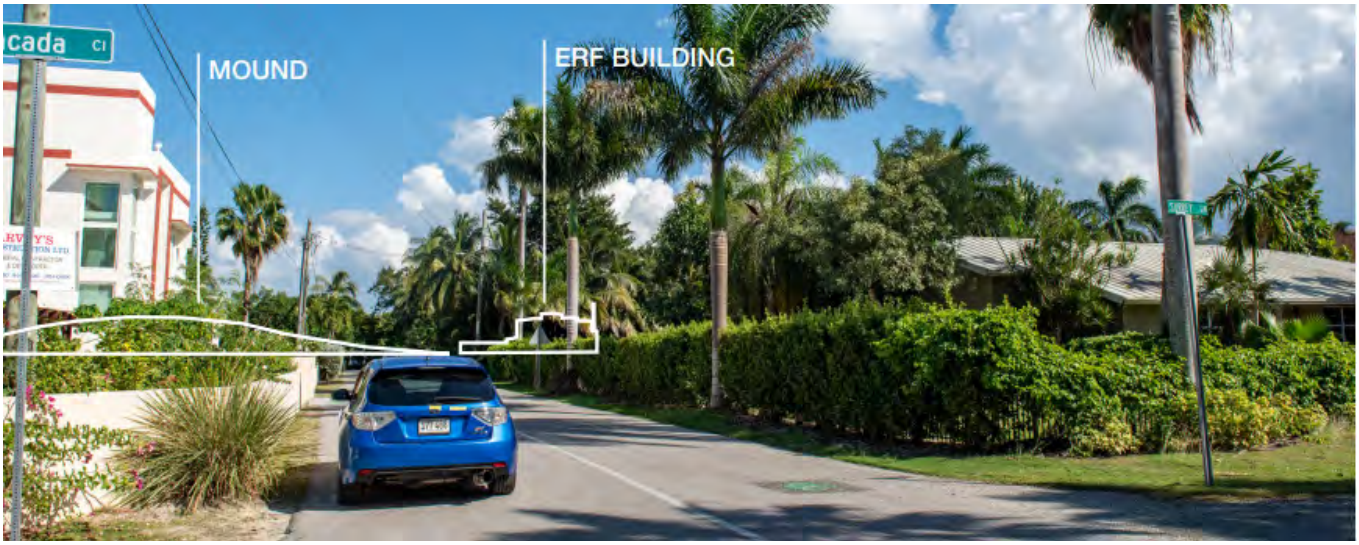

Photo 7.6 Artistic impression showing the Project from viewpoint location 3

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 15 VP03 assessment

Criteria	Comments
Location and view direction	Location (MGA Zone 55); 19.310064N 81.381961W VP03 is situated 650 meters from the Project and is facing in an eastern direction. This viewpoint is representative of views experienced by residents of Marbel drive and the users of the road to access the joining roads of Jacada Close and Surrey Lane.
Description of existing view	In the image's foreground, the main feature is a road running through the neighbourhood, flanked on the left side by a single-story building painted white with a terracotta linear detail. The building is surrounded by a garden wall that borders the road, creating a sense of enclosure and privacy. Behind the wall, a variety of vegetation can be seen peeking over the top; a single species of sedge and a small linear-shaped grassed area on the exterior provides a buffer between the wall and the road. A solitary palm tree can be seen in the midground on the left. On the right-hand side of the image, the foreground is dominated by lush and verdant vegetation composition. A well-maintained hedge lines the road on this side, with equally spaced palm trees set into the hedge. A single-story dwelling can be seen nestled among the greenery, creating a sense of seclusion and privacy. The composition's vanishing point comprises a mix of mature tree species.
Anticipated change to view	The Project will not be visible from this location, due to the vegetation blocking the view. Refer to Photo 7.6.
Sensitivity to change	The sensitivity to change would be **High** as occupiers of residential properties, at home or going to or from, with long viewing periods, within close proximity to the proposed development; Communities that place value upon the landscape and enjoyment of views of their setting.
Magnitude of change	The magnitude of change would be **Negligible** as minor loss or alteration to one or more key view elements, features or characteristics, or the introduction of components that may be visible but may not be uncharacteristic within the existing view.
Significance of effect	The significance of effect will be **Minor** as sensitivity to change is High and magnitude of change is Negligible.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

7.1.4 Viewpoint 4: Residential properties on Lakeside Villas

VP04 is located in Lakeside Villas carpark looking east towards the Project site across the Esterly Tibbetts Highway. The assessment for VP04 is discussed in Table 7.5. The existing view is illustrated in Photo 7.7 and artistic impression illustrating the Project design are shown in Photo 7.8.

Photo 7.7 Viewpoint 4: Located in Lakeside Villas car park looking east towards Project site across Esterly Tibbetts Highway - existing view

Photo 7.8 Viewpoint 4: Lakeside Villas car park looking east towards Project site across Esterly Tibbetts Highway - Artistic Impression

GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 16 VP04 assessment

Criteria	Comments
Location and view direction	Location (MGA Zone 55); 19.308675N 81.377910W VP04 is situated 250 meters from the Project and is facing in an eastern direction. This viewpoint is representative of views experienced by the residents and visitors of Lakeside Villas that use the carparking spaces.
Description of existing view	A car park is featured in the foreground to mid-ground of the image, displaying various car models. The border of the car park is lined with palm trees, and trim liner hedges are maintained between the spaces. Moving towards the centre midground, the visual frame is created by the palm trees lining the area, providing a clear view of the mound of the GTLF. The central midground is free of vegetation hedges but is instead adorned with palm trees, three mature, three recently planted and of small stature, that contributes to the frame. To the left-hand side of this palm tree-lined centre view, a mixed-height hedge composed of various species is visible. The crash barrier running from left to right in the centre midground indicates the presence of a freeway, with a chain-link fence visible behind it, marking the boundary of the project site. Directly behind the fence is a hedge consisting of an unknown species. A series of utility wires run from left to right, with a single lamp post positioned at the centre of the frame.
Anticipated change to view	In the centre midground to the mid right where the vegetation and tree line meet, a series of large industrial buildings and ventilation stack will be visible. The buildings are visually located behind the existing vegetation line and would be partially obscured from view with the stack being the most visible from this location. Plumes of white steam and gas would be exhausted from the stack during operation, which would make it more visible.
Sensitivity to change	The sensitivity to change would be **High** as occupiers of residential properties, at home or going to or from, with long viewing periods, within proximity to the proposed development; Communities that place value upon the landscape and enjoyment of views of their setting.
Magnitude of change	The magnitude of change would be **Low** as minor loss or alteration to one or more key view elements, features or characteristics, or the introduction of components that may be visible but may not be uncharacteristic within the existing view.
Significance of effect	The significance of effect will be **Moderate** as sensitivity to change is High and magnitude of change is Low.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

7.1.5 Viewpoint 5: Camana Bay Observation Tower

VP05 is located on the Camana Bay Observation Tower (approximately 74 feet (22.5 m) high). The assessment for VP05 is discussed in Table 7.6. The existing view is illustrated in Photo 7.9 and artistic impression illustrating the Project design are shown in Photo 7.10.

Photo 7.9 Viewpoint 5: Camana Bay Observation Tower existing view

Photo 7.10 Artistic impression showing the Project from viewpoint location.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 17 VP05 assessment

Criteria	Comments
Location and view direction	Location (MGA Zone 55); 19.321814N 81.377712W Elevation: 74 feet (22.5 m) VP05 is situated approximately one kilometre from the Project and is facing in a southern direction. This viewpoint is representative of views experienced by users of the observation tower.
Description of existing view	On the left-hand side of the image's foreground, there are two tall palm trees with a linear planting of smaller palm trees behind them, extending further into the mid-ground. A similar planting style can be seen on the far-right side of the image, bordering one of the buildings. The image's foreground, middle ground, and parts of the background feature buildings of various heights and designs, all showcasing a contemporary architectural finish. In the centre of the mid-ground, a tall office building stands out. Towards the right side of the centre of the image, an open space reveals a view of the vegetation line, creating a contrast to the otherwise urban and artificial environment.
Anticipated change to view	The Project will not be visible from this location, due to the office building obscuring the buildings and stack from view.
Sensitivity to change	The sensitivity to change would be **High** as occupiers of residential properties, at home or going to or from, with long viewing periods, within proximity to the proposed development; Communities that place value upon the landscape and enjoyment of views of their setting.
Magnitude of change	The magnitude of change would be **Negligible** as almost imperceptible or no change in the view as there is little or no loss of/or change to the elements, features, or characteristics of the view.
Significance of effect	The significance of effect will be **Minor** as sensitivity to change is high and magnitude of change is Negligible.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

7.1.6 Viewpoint 6: Tall residential properties on Seven Mile Beach

VP06 is taken from a tall residential building on Seve mile beach located on Snooze Lane. The assessment for VP06 is discussed in Table 18 VP06 assessment . The existing view is illustrated in Photo 7.11 and artistic impression illustrating the Project design are shown in Photo 7.12 and Photo 7.13.

Photo 7.11 Viewpoint 6: Tall residential properties on Seven Mile Beach on Snooze Lane looking east – existing view

Table 18 VP06 assessment

Criteria	Comments
Location and view direction	Location (MGA Zone 55); 19.311931N 81.385333W Elevation: 74 feet (22.5 m) approx. VP06 is situated approximately one kilometre from the Project and is facing in an eastern direction. This viewpoint is representative of views experienced by the residences of the building.
Description of existing view	The photo taken from an elevated position provides a panoramic view of the project site. In the foreground, a public service building with a roof and a surrounding car park is visible. Towards the centre of the image, a main road runs horizontally from right to left. The middle ground shows an urban setting with substantial vegetation, mainly consisting of palm trees planted linearly along the boundary lines of the properties and the road. The central background offers a clear view of the GTLF, with the sea visible beyond it. On the right side of the GTLF, the urban matrix can be seen extending towards the vanishing points of the composition while non-human made elements rise above the horizon line.
Anticipated change to view	In the centre background a series of large industrial buildings and a ventilation stack will be visible. Plumes of white steam and gas would be exhausted from the stack during operation, which would make it more visible.
Sensitivity to change	The sensitivity to change would be **High** as the occupiers of residential properties, at home or going to or from, with long viewing periods, within proximity to the proposed development; Communities that place value upon the landscape and enjoyment of views of their setting.
Magnitude of change	The magnitude of change would be **High** as a substantial/obvious change to the existing view due to total loss of, or change to, elements, features, or characteristics of the view. Would cause a view to be permanently changed and its quality diminished.
Significance of effect	The significance of effect will be **Major** as sensitivity to change is High and magnitude of change is High.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. Table 19 VP07 assessment

Criteria	Comments
Location and view direction	Location (MGA Zone 55); 19.311931N 81.385333W Elevation: 74 feet (22.5 m) approx. VP07 is situated approximately one kilometre from the Project and is facing in an eastern direction. This viewpoint is representative of views experienced by the tourists and staff of the cruise liners.
Description of existing view	The photo taken from an elevated position provides a panoramic view of the project site. In the foreground, the sea and bay that make up seven-mile beach is viewable. Towards the centre of the image, seven-mile beach and its hotels, residencies and small port can be seen. The middle ground shows an urban setting with substantial vegetation. The central background offers a clear view of the GTLF, with the sea visible beyond it.
Anticipated change to view	In the centre background a series of large industrial buildings and a ventilation stack will be visible. Plumes of white steam and gas would be exhausted from the stack during operation, which would make it more visible.
Sensitivity to change	The sensitivity to change would be **High** as the occupiers of residential properties, at home or going to or from, with long viewing periods, within proximity to the proposed development; Communities that place value upon the landscape and enjoyment of views of their setting.
Magnitude of change	The magnitude of change would be **High** as a substantial/obvious change to the existing view due to total loss of, or change to, elements, features, or characteristics of the view. Would cause a view to be permanently changed and its quality diminished.
Significance of effect	The significance of effect will be **Major** as sensitivity to change is High and magnitude of change is High.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. 7.1.8 Viewpoint 8: North Sound

VP08 is taken from a boat located approximately one mile (1.5 km) off the coast of the North Sound lagoon. The baseline and effect assessment for VP08 is discussed in Table 20. The existing view is illustrated in Photo 7.16 and the artistic impression illustrating the Project design are shown in Photo 7.17.

Photo 7.16 Existing view looking west

Photo 7.17 Artistic render showing the project from the viewpoint.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 20 VP08 assessment

Criteria	Comments
Location and view direction	Location (MGA Zone 55); 463235.771 E, 2137471.258 N Elevation: Not provided VP08 is situated approximately one and a half kilometres east of the Project and is looking west. This viewpoint is representative of views experienced by the users of the North Sound Lagoon.
Description of existing view	The image's composition consists of the expansive water of the North Sound Lagoon across the foreground, the land of Grand Cayman Island in the mid-ground, creating the thin horizon line, with the expansive heavily clouded blue sky above. The water's surface is textured by the wind, evident in the choppy and undulating waves. The midground of this composition depicts the North Sound Lagoon's mangroves, with dense dark green vegetation creating a strong delineation between the turquoise sea and dark green land. The mangroves upper vegetation has varied heights creating a filtered horizon line with the sky. The views are predominately to natural elements, with the exception of the landfill mound to the right of view. To the left of the view stand two communication towers that rise above any existing element in the landscape, above the horizon line.
Anticipated change to view	A series of large industrial buildings and a ventilation stack will be visible in the central background. Plumes of white steam and gas may be exhausted from the stack during operation, making it more visible. However, from this location, the buildings and stack sit below or are equal to the height of communications towers within the viewpoint. The Project is visually located behind the mangroves
Sensitivity to change	The sensitivity to change would be **High** for users and communities of the North Sound who hold a appreciation for the landscape's significance and the scenic views of their surroundings.
Magnitude of change	The magnitude of change is deemed **High**, as it would lead to a permanent alteration of the landscape, causing a reduction in its overall quality.
Significance of effect	The significance of effect will be **Major** as sensitivity to change is High and magnitude of change is High.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

7.2 Other Views

Photo 7.18 Additional view of Looking East down Courts Road from Eastern Avenue

Photo 7.19 Additional view of typical residential area within Zone 3

8. Construction effects

At present, it is anticipated that the construction period will be over a 24–33-month period from 2024 to 2027. During this period, construction activities may be within view, including the temporary presence of cranes, concrete pumps, and other machinery, as well as construction compounds and other ancillary structures.

The presence of the above elements is not anticipated to be significantly out of character within the existing visual environment due to the location of the Project within an industrial area. Furthermore, existing and anticipated future construction sites are expected to be present within the surrounding visual environment. The visual effects associated with construction are temporary and therefore do not influence the overall ratings of the viewpoints in this report.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

9. Mitigation measures

The below mitigation measures are to be considered to reduce the effects of the project. These include:

– Consider colour gradations to reflect the surrounding sky, landscape, and seascape.
– Consider materials of low reflectivity.
– Consider façade treatment or alternative use to create visual variation (such as artistic mural, outdoor cinema, rock climbing etc.).

10. Conclusion

This Landscape and Seascape Visual Assessment has been undertaken to identify the potential effects of the Project based on its concept design.

The Project area is located to the north of central George Town towards the western coast of Grand Cayman, immediately south-west of the existing George Town Landfill. The Project site sits within the identified LCZ2, bordering with LCZ3 and SCZ4. The scale and location of the Project within this zone which already contains similar land uses reduces the potential for significant direct landscape effects upon Grand Caymans key landscape and townscape characteristics.

A total of five landscape and seascape character zones were identified within the study area: Tourism foreshore and George Town centre (LCZ1), Industrial, waste and airport (LCZ2), Residential settlement (LCZ3), Mangroves and recreation (SCZ4), Caribbean Sea and North Sound Lagoon (SCZ5). In terms of indirect landscape effects upon surrounding character areas, these will primarily be a consequence of a visual effect i.e., where some components of the Project during the construction and/or operation periods will become visible in outward views available from these character areas. However, the likely level of screening provided by built form within the northern and central parts of George Town to the south; and the development associated with Seven Mile Beach and Camana Bay to the west allied with the context within which the development will be viewed (i.e. within a zone in which industrial development and construction activities are common), will reduce the potential for the Project to have a significant influence upon the character and key characteristics of these neighbouring landscape and seascape character areas.

LCZ2 Industrial, waste and airport was found to have a **Moderate** effect associated with location of the Project within LCZ2, along with the tall stack height (158 ft or 48.1 m) which will have high visibility. The landscape and seascape character zones LCZ3 and SCZ5 were found to have **Minor** landscape character effects, due to their high sensitivity and negligible magnitude of change. LCZ1 and SCZ4 were found to have **Negligible** landscape character effects as a result from the Project, due to their medium sensitivity and negligible magnitude of change.

Sensitive visual receivers in the study area include residents, pedestrians, road users, cruise liner users, and workers of the industrial zone. Eight viewpoint locations were chosen to assess the visual effects of the Project on sensitive receivers within the study area. Visual effects were assessed using panoramas of the existing view and seven artistic impressions were created illustrating the proposed view of the Project, from eight viewpoint locations. The assessment found that the Project would have a **Major** visual effect on VP02, VP06, VP07 and VP08, due to the high sensitivity of residents on Brushy Avenue and Woodlake Drive, residents on Seven Mile Beach and tourists and staff of the cruise liners off Seven Mile Beach, and users of North Sound Lagoon. A **Moderate** visual effect is experienced from VP04, while VP01, VP03 and VP05 experience a **Minor** overall visual effect.

Mitigation measures proposed for the construction and operational stages should be incorporated into detailed design and construction management plans to reduce visual effects. Mitigation measures such as screening vegetation may be useful locally to screen views from the residential areas, however the size of the project as seen from VP06 and VP07 would not be mitigated by this approach.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

The following Table 21and Table 22 provide a summary of landscape and visual effects for the Project.

Table 21 Summary of landscape effects

LCZ	Description	Sensitivity to change	Magnitude of change	Overall Rating
LCZ1	Tourism foreshore and George Town centre	Medium	Negligible	**Negligible (Not significant)**
LCZ2	Industrial, waste and airport	Low	High	**Moderate (Probably significant)**
LCZ3	Residential settlement	High	Negligible	**Minor (Not significant)**
SCZ4	Mangroves and recreation	Medium	Negligible	**Negligible (Not significant)**
SCZ5	Caribbean Sea and North Sound Lagoon	High	Negligible	**Minor (Not significant)**

Table 22 Summary of visual effects

Viewpoint	Location	Sensitivity to change	Magnitude of change	Overall Rating
VP01	National Galley of the Caymans Island	Low	Medium	**Minor (Not significant)**
VP02	Viewpoint location 2: United Pentecostal Church	High	High	**Major (Significant)**
VP03	Residential properties on Marbel Drive	High	Negligible	**Minor (Not significant)**
VP04	Residential properties on Lakeside Villas	High	Low	**Moderate (Probably significant)**
VP05	Camana Bay Observation Tower	High	Negligible	**Minor (Not significant)**
VP06	Tall residential properties on Seven Mile Beach	High	High	**Major (Significant)**
VP07	Cruise Liner anchored off Seven Mile Beach	High	High	**Major (Significant)**
VP08	North Sound Lagoon	High	High	**Major (Significant)**

1. Introduction

The Cayman Islands Government in partnership with DECCO Consortium (the Proponent) is proposing the development of an Integrated Solid Waste Management Facility (ISWMS) in the Cayman Islands, on Grand Cayman ('the Project'). The following report details the Air Quality Assessment (Assessment) that was conducted in support of the Project's Environmental Impact Assessment (EIA).

Each year, approximately 115,000 tons of solid waste is produced in the Cayman Islands, with the overwhelming majority of the material presently being managed by the George Town Landfill (GTLF). This landfill capacity is, however, finite and in accordance with the provisions of both the National Solid Waste Management Strategy for the Cayman Islands (2016) and the National Planning Framework (draft for public consultation) (2018), a Terms of Reference was prepared in relation to the proposed development of a replacement ISWMS for the Cayman Islands.

The proposed ISWMS site is located to the north of central George Town towards the western coast of Grand Cayman, immediately south-west of the existing GTLF. The proposed ISWMS is a multi-facility development, including an energy recovery facility (ERF) and supporting non-ERF waste processing, treatment, and disposal facilities. Construction and operation of the ISWMS would allow the existing landfills in George Town, Cayman Brac and Little Cayman to be closed and remediated. This Assessment was prepared to provide an assessment of the air quality impacts resulting from the proposed Project. The air quality impacts were compared to relevant standards and guidelines and to the existing air quality conditions. Using monitored background air quality data, the Assessment discusses the existing air quality in the vicinity of the proposed Project and the potential impacts of the proposed Project on local air quality.

1.1 Overview of Report Contents

This Report describes the existing air quality conditions in the area of the Proposed ISWMS Site (Site) followed by an analysis of potential effects, mitigation measures and net effects of the Project on the air quality. The key components of the Report are as follows:

– Study methodology
– Applicable regulatory requirements
– Existing ambient air quality
– Dispersion Modelling
– Emission Inventory
– Comparison of model predictions to applicable air quality criteria

2. Study Methodology

During the Project's operational time, airborne dispersion of contaminants will serve as the main conduit for air contaminants to reach human and sensitive receptors.

The assessment of the Project's effect on air quality was performed by conducting dispersion modelling to predict the downwind concentrations of air contaminants and comparing these predictions to regulatory standards, and guidelines. There are several steps to building a plume dispersion model. The preparation of a representative emissions inventory is key to a successful modelling prediction.

The assessment of air quality effects related to the Project consisted of the following elements:

– Assessment of existing baseline ambient air quality conditions for Chemicals of Potential Concern (CoPCs) from the existing air emissions sources at the Site and its vicinity through emission inventory and air monitoring measurements.
– Compilation of emissions estimates for CoPCs from point and mobile sources in the proposed Project.
– Dispersion modelling of the existing emissions from the Site and significant sources identified in the vicinity to establish a baseline model and compare to monitored data.
– Comparison of dispersion model predictions to ambient air quality criteria as well as evaluation of the incremental change in air quality associated with the Project.

The impact assessment methodology primarily consisted of ensuring that there would be no exceedances to the air quality limits defined in the air quality criteria, defined further in Section 3.1. This was the main consideration for whether the air quality changes would have a significant impact.

2.1 Timeframes Considered for Analysis

The following timeframes were considered for dispersion modelling, in order to assess potential impacts on the air quality.

Baseline

Existing emission sources at the Site and its vicinity would be contributing towards the baseline or background air concentrations.

Construction Phase

The time during which the construction activities occur on the site to setup the facilities associated with the Project. Predominantly emission from the construction phase is expected to be dust.

Operational

This phase includes the fully operational state of the Project. Estimated maximum emissions of the CoPCs are modelled and the maximum offsite concentrations are added to the baseline monitored concentrations for a cumulative impact assessment.

2.2 Study Area

For the purpose of this Assessment, an Air Quality Study Area (Study Area) was defined to extend up to 10 km in all four cardinal directions. Air quality impacts outside the Site Property line are assessed. Onsite impacts are not included in the scope of this Assessment.

2.3 Contaminants of Potential Concern

A wide range of substances can be emitted from the operations associated with the Project. Facilities associated with the Project include the following:

– An Energy Recovery Facility (ERF) for the treatment of Municipal Solid Waste (MSW)
– A Green Waste Facility for outdoor processing (composting and mulching) of organic waste
– An End-of-Life Vehicle (ELV) and Scrap Metal Processing Facility
– A Construction and Demolition (C&D) Waste Facility
– A Bottom Ash Processing Facility
– A Medical Waste Processing Facility
– A Landfill Gas Facility and

– A Residual Waste Landfill

The expected emissions, based on the Project-specific design and operation, formed the basis of selecting the substances for evaluation. A comprehensive list of CoPCs was developed in consultation with the Environmental Assessment Board (EAB) and published in the Terms of Reference and Air Quality Method Statement, included in Appendix A. The CoPCs are listed below.

– Dioxins and Furans (PCDD/PCDF)
– Total Dust, assessed as:
  - Particulate (particulate matter < 10 microns [PM_{10}])
  - Particulate (particulate matter < 2.5 microns [$PM_{2.5}$])
– Volatile organic compounds (VOC) as Total Organic Carbon (TOC)
– Hydrogen Chloride (HCl)
– Hydrogen Fluoride (HF)
– Sulphur Dioxide (SO_2)
– Oxides of Nitrogen (NOx) expressed as NO_2
– Carbon Monoxide (CO)
– Heavy Metals:
  - Cadmium (Cd)
  - Thallium (Tl)
  - Mercury (Hg)
  - Antimony (Sb)
  - Arsenic (As)
  - Lead (Pb)
  - Chromium (Cr)
  - Cobalt (Co)
  - Copper (Cu)
  - Manganese (Mn)
  - Nickel (Ni)
  - Vanadium (V)

Dust was assessed as $PM_{2.5}$ and PM_{10}. In addition, as part of the odour assessment, hydrogen sulphide (H_2S) from the landfilling activities and the surrounding potential odour sources was identified as a compound of concern. Polycyclic Aromatic Hydrocarbons (PAHs) was also included as a compound of concern due to fuel combustion background sources. The most significant VOC from the fuel combustion sources is benzene and it was used as the indicator for VOCs.

3. Regulatory Framework

The following section includes a review of the regulatory framework that governs the ambient air quality as well as the industrial emission limits.

3.1 Ambient Air Quality

The standards that were used for the determination of compliance with ambient air criteria were taken from the **UK National Air Quality Objectives**. These applicable air quality standards and associated time averaging periods are provided in Table 1.

Although the **UK National Air Quality Objectives** has an air quality standard for H_2S, the Ontario (Canada) 10-minute limit for odour is used because the purpose of assessing H_2S for this study is in relation to an odour assessment.

There are no ambient air quality limits for dioxins and furans in the **UK National Air Quality Objectives**. For reference, the Ontario limits have been used which is based on WHO guidance. Industrial Emission Limits

The primary EU tool for controlling pollutant emissions from industrial units, such as waste incinerators and Energy Recovery Facilities (ERF), is the EU Industrial Emissions Directive (IED – 2010/75/EU). By lowering harmful industrial emissions throughout the EU, particularly through improved application of Best Available Methods, it strives to ensure a high degree of protection for human health and the environment as a whole. The ERF included in the Project will have one primary exhaust stack for emissions from the ERF activities, referred to hereafter as the “ERF stack”. The applicable EU emission standards for the ERF stack is summarized in Table 2.

4. Existing Baseline Conditions

The following sections describe the existing physical environment of the Study Area.

4.1.1 Topography

The general topography of the study area is flat landscape with mangrove swathes. The general land use in the area is a mix of industrial and residential developments. The highest point on Grand Cayman, is about 70 feet above sea level. There are no rivers located on the island. The coasts are usually shielded by offshore reefs and, in some locations, a mangrove fringe that occasionally reaches inland marshes.

4.1.2 Climate

All year long, the Cayman Islands have a tropical climate that is hot and humid. The northeast trade winds provide a dry, comparatively cold season from late November to mid-April, and a wet, muggy season from late April to early November. The Cayman Islands see relatively lower winter temperatures than summer ones. The islands occasionally experience cool breezes from the United States from December to March, which can cause the nighttime temperature to drop to about 15 °C (59 °F). Maximum temperatures during the rainy season are around 32 °C (90 °F).

According to the Cayman Island national Weather Service, the annual average temperature is about 28°C, with maximum temperatures reaching up to 33°C and lowest temperatures of 18°C. The Grand Cayman on an annual basis receives about 1400 mm of rainfall, with an annual average relative humidity of 77%. The predominant winds are mostly blowing from the east to the west, with an average wind speed of 4.6 m/s.

4.1.3 Sensitive Receptors

The Site is located in a predominantly industrial area with sensitive receptors such as residential areas and schools located primarily to the southwest, west and northwest. The following sensitive receptors, as shown in Figure 1, were included as part of the Assessment.

– Locations within the Lakeside Development (residential dwellings immediately west of the ISWMS development, on the opposite side of the Esterly Tibbetts Highway).
– Locations within the OLEA residential development approximately 800 m north of the ISWMS development.

– Properties on Parkside Close (residential dwellings approximately 800 m to the northwest of the ISWMS development).
– The Cayman International School (educational institute approximately 800 m to the north of the ISWMS development).
– The Seven Mile Beach corridor which starts approximately 1,500 m to the northwest of the ISWMS development, which includes residential tourism properties.
– Health City-Camana Bay's Cancer Research facility approximately 600 m to the north of the ISWMS development, estimated to be operational by the year 2024.
– Jasmine Hospice facility located on West Bay Road, approximately 1,000 m west of the ISWMS development.
– Royale Medical and Wellness Center is a medical laboratory located approximately 1,000 m west of the ISWMS development.
– Cayman Medical located approximately 900 m south of the ISWMS development.
– George Town Primary School located approximately 900 m southwest of the ISWMS development

4.1.4 Background Air Quality

An ambient air monitoring programme was run as part of the Environmental Impact Assessment (EIA) for the Cayman Islands Integrated Solid Waste Management System (ISWMS). The Cayman Islands Government and their consultants assessed an Air Quality Method Statement (Method Statement) that GHD had submitted. On October 8, 2021, the Method Statement was reviewed, approved, and given comments. An ambient air monitoring programme (AAMP) was developed to establish the baseline ambient air concentrations of air contaminants in the Study Area. GHD, Valley Environmental Services (VES), Dart Enterprises Cayman, and the Department of Environmental Health (DEH) all contributed to the creation and management of the AAMP.

The list of air pollutants that were tracked and measured for the programme included the CoPC emissions that are anticipated to come from new sources connected to the ISWMS plant as well as other emissions that are already being produced by fuel combustion emissions sources in the Study Area, such as nitrogen oxides. The potential emission sources that make contributions to the current baseline are shown in Figure 2.

On October 24, 2021, the AAMP was launched and lasted for about four months, with around one month of the wet season and three months of the dry season. Staff from Dart and DEH managed the AAMP after GHD and VES completed the assembly of the monitoring stations and initial calibration of the monitoring apparatus. GHD and VES gave training on all facets of the equipment being utilised in the AAMP prior to the start of the Program. GHD and VES provided remote support and had access to the CEM data during the monitoring period. The Ambient Air Monitoring Report prepared by GHD in March 2023 describes the AAMP in detail, included in Appendix B.

4.1.4.1 General Description and Purpose of Each Monitoring Station

The choices for the sampling sites and technique were based on a hybrid strategy that combined Ontario (Canada) monitoring methods, USEPA ambient air monitoring methods, and United Kingdom/European Union (UK/EU) ambient air monitoring methods. Labs in North America were selected for analysis of collected samples because of their proximity to ensure compliance with sample holding times. The methods used in the UK/EU, USEPA, and Ontario for sampling, analysis, and continuous/passive ambient air monitoring are generally relatively comparable. There were three types of monitoring: passive, intermittent, and continuous. The seven locations for the air monitoring stations are shown in Figure 3, along with the parameters that were monitored at each station.

Station 1 – Cox Lumber

Station 1 was the primary monitoring station, consisting of an air-conditioned container that housed the following Federal Reference Method (FRM)/Federal Equivalent Method (FEM) and associated equipment:

– Teledyne API (TAPI) T200 NO_x Chemiluminescence analyzer.
– TAPI T300 CO Gas Filter Correlation analyzer.

- TAPI T100 SO2 UV Fluorescence analyzer.
- MetOne Beta Attenuation Monitor (BAM) 1020 Continuous $PM_{2.5}$ Monitor.
- Zero Air Generator.
- EPA Protocol 1 Calibration Gases (NO, SO_2 and CO).
- HF and HCl impinger samplers.
- A 20 ft meteorological tower (above the roof of the container) with an RM Young wind speed (WS) and wind direction (WD) monitor including relative humidity (RH), and ambient temperature (AT).
- A dedicated sample recovery area including a refrigerator for interim storage of samples requiring cool storage.

A rooftop area with a railing also housed non-continuous samplers such as:

- FRM high volume PM_{10} sampler for the collection of PM_{10} and metals in the PM_{10} fraction for 24-hours every six days.
- FRM medium volume (PUF) sampler for the collection of semi-volatiles including PCDD/PCDF and PAH compounds for 24-hours every six days.
- Summa canister for the collection of VOCs using Method TO 15 for 24-hours every six days.
- Passive monitors for NO_2 and SO_2 for correlation purposes.

This station was located according to the criteria for the location of a background monitoring station away from major roads and trees and was not influenced significantly by any specific emissions source. The station was located downwind of the future site of the ISWMS and the ERF and other significant emissions sources in the area.

Figure 4, below, shows a photograph of the Cox Lumber monitoring station.

Figure 4 Cox Lumber Monitoring Station

Station 2 – Paddington Place

Station 2 was used for passive monitoring of NO_2 and SO_2 from industrial areas, the Caribbean Utilities Company (CUC), and road traffic emissions. Paddington Place was located close to the Esterly Tibbetts highway and a major roundabout.

Station 3 – George Town Primary School

Station 3 was used for passive monitoring of NO_2 and SO_2 for sensitive receptors at the George Town Primary school.

Station 4 – OPY 20

Station 4 was used for passive monitoring of NO_2 and SO_2 and continuous monitoring of PM_{10} and WS/WD from the downtown core.

Station 5 – Lakeside

Station 5 was used for passive monitoring of NO_2 and SO_2, continuous monitoring of PM_{10} and H_2S, and WS/WD near sensitive receptors at this residential complex located directly downwind of the George Town Landfill (GTLF). The Lakeside monitors are also located very close to the edge of Esterly Tibbetts highway and will therefore show impacts from road traffic.

Station 6 – Cayman International School (CIS)

Station 6 was used for passive monitoring of NO_2 and SO_2 for the sensitive receptors at CIS.

Station 7 – Laundry

Station 7 was used for continuous monitoring of H_2S from the Wastewater Treatment Plant (WWTP) and other H_2S sources upwind of the GTLF, as well as continuous monitoring of WS/WD.

4.1.4.2 Background Values

The background concentrations for the air contaminants measured at each Station during the 4-month air monitoring campaign are summarized in Table 3. For the various air contaminants and their averaging periods (except for the annual averaging period), the 90th percentile value was used to represent the background concentration at each station. For the air contaminants with annual limits, the average background concentration from the full range of data collected was used. To estimate the background concentration for the Study Area for compounds that were monitored at multiple monitoring stations, the average of the 90th percentile values were used, as summarized in Table 3.

NO_2

The NO_2 concentrations were measured at Station 1 with CEMS. Passive samples for NO_2 were monitored at six Stations (1 through 6), including a co-located passive sampler at Station 1. The 1-hour and annual background concentrations are provided in Table 3. Combustion gas emissions were relatively stable with low concentrations measured throughout the monitoring period.

CO

The TAPI CEM located at Station 1 was used for the baseline concentrations for CO. The 8-hour background concentration for CO is provided in Table 3.

SO_2

Continuous samples for SO_2 were monitored at Station 1 and passive samples were collected at six Stations (1 through 6), including a co-located passive sampler at Station 1. The 1-hour, 24-hour and 15-minute background concentrations are provided in Table 3.

$PM_{2.5}$

The BAM 1020 CEM with the $PM_{2.5}$ cut cyclone located at Station 1 was used for the baseline concentrations for $PM_{2.5}$. The $PM_{2.5}$ annual background concentration is provided in Table 3.

H_2S

H_2S was monitored continuously upwind and downwind of the GTLF at Station 7 and Station 5 respectively. These stations were located to monitor specific sources of H_2S, namely the WWTP and the GTLF, so they may not be representative of true background concentrations of areas outside of the influence of these two specific sources. H_2S data collected at Station 5 was potentially influenced by a large holding tank containing sewage located close to the instrument. The comparison of this limit to H_2S concentrations measured at Lakeside Station 5 produced the only air quality limit exceedance during the program. This exceedance was likely influenced by the location of the monitor as noted above. It should also be noted that H_2S is not considered as a by-product of the emissions from the ERF, so ambient concentrations should be lower after construction of the ISWMS

PM_{10}

PM_{10} was measured non-continuously from Station 1 every 6 days for a 24-hour period for the monitoring duration, for a total of 20 samples. PM_{10} was also measured continuously from Stations 4 and 5. The continuous PM_{10} concentrations from these two stations show the impacts of vehicle traffic in the downtown areas and the Esterly Tibbetts highway. The 24-hour and annual PM_{10} background concentrations from the continuous and non-continuous samplers are provided in Table 3.

Metals

Metals were measured non-continuously from the PM_{10} fraction at Station 1 every 6 days for a 24-hour period for the monitoring duration for a total of 20 samples. The annual background concentrations for cadmium, arsenic, lead, and nickel are provided in Table 3.

PCDD/PCDF

Dioxins and furans were measured non-continuously at Station 1 every 6 days for a 24-hour period for the monitoring duration for a total of 20 samples. The 24-hour dioxin and furan background concentrations are provided in Table 3.

PAHs

PAHs were measured non-continuously at Station 1 every 6 days for a 24-hour period for the monitoring duration, for a total of 20 samples. The PAH standard is based on benzo(a)pyrene (BaP) as noted in Table 1. The annual BaP background concentration is provided in Table 3.

VOCs

VOCs were measured non-continuously at Station 1 every 6 days for a 24-hour period for the monitoring duration, for a total of 19 samples. Benzene is the VOC of most concern for this Assessment because it is present in fuel combustion exhausts, the primary sources of VOCs in the area, and it has a low air quality standard. The ambient air standard for benzene is shown in Table 1. The hourly and annual benzene background concentrations are provided in Table 3.

HF/HCl

HCl/HF were measured non-continuously at Station 1 every 6 days for a 24-hour period for the monitoring duration, for a total of 20 samples. The hourly background HCl concentration and the hourly and annual background HF concentrations are provided in Table 3.

Passive Monitoring for NO_2 and SO_2

Passive samples for NO_2 and SO_2 were deployed at Stations 1, 2, 3, 4, 5 and 6 for nine (9) two-week periods. The hourly and annual NO_2 concentrations from each Station are provided in Table 3. The 15 minute, 1-hour, and 24-hour SO_2 concentrations from each Station are provided in Table 3.

Odour

An odour assessment survey was conducted by GHD, DEH and Dart staff during daylight and after sundown as part of the background monitoring, and the following sources were assessed qualitatively:

– CUC
– WWTP
– GTLF
– Mangroves and shoreline areas
– Medical Waste Incinerator (MWI)
– Asphalt Plant

In addition, the following sensitive receptor locations were assessed qualitatively for odour:

– Cayman International School
– Lakeside Condominiums

Details of the odour assessment survey are included in the Ambient Air Monitoring Report. The odour assessment concluded that once the Project becomes operational there will be a reduction in odour due to diversion of waste from landfilling activities which can generate fugitive odours from the working face and from landfill gas. Therefore, the implementation of the ISWMS should result in less odour emissions from the Site.

There is a potential for odour emissions from the Green Waste Facility (GWF) composting area. According to the “Guidance on the Assessment of odour for planning (Version 1.1)” by the Institute of Air Quality Management, odour emissions from aerated green waste composting is classified as 'moderately offensive'. However, the facility will only be used to process leaf and yard waste, which is a small subset of the types of waste typically included in a composting facility. The material received is significantly less odourous than other types of green waste such as food and animal byproducts. Odour emitted from yard waste compost is described as 'earthy' and is therefore categorized as 'less offensive'. The nearest sensitive receptors to the GWF are properties approximately 300 meters southwest of the development. Per the UK Environment Agency's policy on composting, there is a recommended separation distance of 250 meters buffer separating the nearest sensitive receptors. This policy is in relation to bioaerosols which would be a strong contributor to potential odour effects. Additionally, the ISWMS facility will conform to a Code of Good Practice to adopt operations and mitigation measures to control activities that may generate and affect the release of odours. In addition to the setback distance and odour management procedures, the frequency of the historical wind data is observed to have less than 2% 'calms' which would be the wind condition most likely to propagate odour complaints due to low dispersion. There may also be some potential for low dispersion in low wind conditions when the wind is blowing from the northeast direction. Wind from the northeast that has a speed less than 3 meters per second occurs less than 3% of the time. These conditions combined with the variable nature of the odour emitted from a composting area would cause any odour impacts to be highly infrequent. The location of the GWF results in an increased separation distance for most of the identified sensitive receptors discussed in Section 4.1.3 compared to the existing GTFL. Therefore, overall, the GWF is not expected to have a significant risk of odour impact and the ISWMS project is expected to be a net reduction in odour impacts.

5. Greenhouse Gas Impact

Currently, GTLF receives over 115,000 tons of solid waste per year. Organic material in waste degrades into methane (CH_4) over time which can emit from landfills. Because methane is a greenhouse gas (GHG) that has 30 times more global warming potential than carbon dioxide over (CO_2) a 100-year period, most landfills, including GTLF, include a landfill gas capture system in which the landfill gas is flared to instead be emitted as carbon dioxide. However even a highly efficient landfill capture system will only capture 60%-90% of CH_4 emissions (United States Environmental

Protection Agency's (US EPA) Benefits of Landfill Gas Energy Projects) (https://www.epa.gov/lmop/benefits-landfill-gas-energy-projects).

By diverting solid waste from a conventional landfill to an energy recovery process, the 10%-40% of uncontrolled CH_4 emissions are avoided from the source and the CO_2 emissions are classified as biogenic as the same CO_2 would have been a natural decomposition of the organic material. Therefore, the energy recovery process would emit significantly less GHG and will offset emissions with every ton of avoided waste to a landfill.

According to the Cayman Islands Department of Environment (DOE), power generation accounts for 65% of Cayman Island GHG emissions as of 2007. In addition to the landfill offsets, surplus power generated through the energy recovery facility will be sold to the Cayman power grid. This will further reduce greenhouse gas emission through the displacement of higher GHG emission power generation.

6. Emissions Inventory

The emissions estimates for the Project and the existing background emissions sources were based on available data of similar units, published emission factors or manufacturer emissions guarantees. The US EPA's Compilation of Air Pollutant Emissions Factors (AP-42) is the primary resource of published emission factors relied on for the emission calculations. Emissions estimates are estimated to be conservative and represent worst-case short-term emissions from each source considered.

6.1 Background Emissions Sources

The purpose of modelling the background emissions was to provide a comparison to the ambient air monitoring program results. The ambient air monitoring program was used to establish the background air quality in the Study Area and the background emissions modelling was used to verify the reasonableness of the background air monitoring data for the primary background air contaminant (NO_x). The modelling of the background NO_x emissions involved many assumptions about the various emissions sources, and GHD took a generally conservative approach.

The background air emissions of concern from the existing emissions sources are primarily related to fuel combustion. The major fuel combustion contaminant is NO_x. The emissions of NO_x, from existing fuel combustion sources (traffic, industry, power generation and airport) was modelled to compare with the measured concentration of NO_x at the ambient air monitoring program stations. The emissions of NO_x were estimated based on best available references for emissions data and published emission factors for the known major contributors (sources) of NO_x in and around the Site. These sources have been identified in Figure 2.

A description of each background source and how the emission estimates are calculated is included in Appendix C.

6.2 Construction

According to the "Guidance on the Assessment of Dust from Demolition and Construction (Version 1.1)" by the Institute of Air Quality Management, a preliminary screening was carried out for the particulate emissions that might occur due to construction activities. The nearest sensitive receptor (a residence) is more than 350 m away from the construction site, and the route taken by construction vehicles is mainly through an industrial area. There are no significant effects likely to occur due to the construction activities at the Project with the implementation of appropriate site-specific dust mitigation plans that will be outlined in the Facility's Environmental Management Plan (EMP). Hence the emissions from the construction phase were not considered as a part of this Assessment.

6.3 Project Operation

This Section provides a description of the proposed ISWMS Facility, and the emissions estimates associated with the significant emissions sources.

6.3.1 Key Features

The proposed ISWMS development consists of various new waste management facilities. The components of the ISWMS subject to this Assessment is as follows:

– Energy Recovery Facility (ERF)
– Non-Energy Recovery Facilities:
  - Site weighbridges
  - Green Waste Processing Facility
  - Construction and Demolition Waste Processing Facility
  - Bottom Ash Processing Facility
  - Abandoned and End-of-Life Vehicle / Scrap Metal Processing Facility
  - Medical Waste Facility
  - Materials Recycling Facility
  - Household Waste Recycling Centre
  - Landfill Gas Facility
  - Residual Waste Landfill
– Ancillary Facilities:
  - Admin Building
  - Maintenance Building

The project layout, and building dimensions are provided in Appendix D.

6.3.2 Energy Recovery Facility

The design life of the new Facility is 25 years. By transforming waste into electrical energy and ash, the Energy Recovery Facility will enhance the recovery and diversion levels in the Cayman Islands. The bottom ash is expected to be recovered through recycling as construction-grade aggregate.

Contract waste will be transported to the ERF by Approved Vehicles, which may include bulk trailers, roll-on/roll-off trucks, and/or waste collection vehicles. The driver of the Approved Vehicles is in charge of emptying the Contract Waste into the reception bunker at the tipping hall.

The Project Site will receive wrapped bales of contract waste from the sister islands of Cayman Brac and Little Cayman. The bales will be held in a storage area next to the Materials Recovery Facility before being moved to the tipping hall for debaling and processing in the ERF.

Two grab cranes will be used to drop the contract waste into the furnace hoppers, where it will then be moved onto the moving grate of the furnace. On the moving grate, waste is burned, producing bottom and fly ash as by products as well as radiant heat and hot flue gases. The steam boiler makes a series of passes where energy in the form of heat is recovered. To lower NOx generation, urea solution is introduced into the first vertical boiler pass. To help with combustion, combustion air is delivered through the grate bars. Before entering the flue gas treatment plant, combustion flue gases flow via the various boiler channels, transferring heat to water- and steam-filled superheater tubes.

Induced draught fans encourage flue gas flow through the boiler, the gas treatment plant, and the bag filter system before being released to the atmosphere through the stack. Combustion air is supplied by primary and secondary air systems. The flue gas treatment facility absorbs dioxins and furans by injecting activated carbon into the acidic gases to neutralise them. To remove particulates, the gas is subsequently passed through bag filters. Flue gas treatment system waste will be stabilised before being placed in the landfill facility.

The steam turbine and linked generator are propelled by superheated steam, which produces power that is used both on the project site and exported to the transmission grid.

As it is transported to the bottom ash storage bunker, bottom ash produced during the combustion process is quenched. From the bottom ash, metals will be removed and recycled.

A logical flow of materials and processing will be provided from input to output by the Facility's design. A secondary weighbridge will be used to weigh recovered ferrous and non-ferrous metals as they are transported to the end-of-life vehicle (ELV) facility for baling and storage before being shipped to metal re-processors. Material that is too large and unusable will either be delivered to the Landfill Facility for disposal or to the Construction & Demolition (C&D) Facility for additional processing.

6.3.3 Energy Recovery Facility Stack

The stack associated with the ERF facility will emit combustion products along with some particulate, metals, HCl, HF, and VOCs. The emissions from this stack will be governed by the EU Industrial Emissions Directive (IED – 2010/75/EU). The manufacturer has guaranteed that the emissions from the ERF stack will not exceed the IED – 2010/75/EU Part 3 air emission limit values for waste incineration plants and the new limits introduced by the Best Available Techniques (BAT) Reference Document for Waste Incineration (2019), Table 5.3. A table of the maximum emission limit values provided by the manufacturer is included in Appendix E. The emissions from the ERF stack are calculated by assuming the maximum IED – 2010/75/EU in-stack concentration limits are emitted at the maximum design flow rate. This conservatively estimates the maximum possible contaminant emissions from the ERF stack based on the manufacturer's guarantee. The contaminant emission rates and stack parameters for the ERF stack are summarized in Table 4.

For CO, the IED – 2010/75/EU in-stack limits have a daily average, half-hour average, and 10-minute average limits. For the purpose of assessing against the air quality standard described in Table 1, which has an 8-hour average, the half-hour average in-stack limit is conservatively used as the maximum emission concentration.

For some of the heavy metals emitted, there are no individual emission guarantees, but a combined emission guarantee. For example, the manufacturer guarantees that Cd and Tl together will be emitted at 0.05 mg/Nm^3 as a conservative approach these heavy metals were each modelled at an emission rate assuming an exhaust concentration 0.05 mg/Nm^3. For arsenic, the manufacturer provided a separate in-stack limit of below 0.1 mg/Nm^3 based on measurements from other similar plants.

Regular emissions monitoring will be conducted in accordance with IED – 2010/75/EU section 2.1. This requires continuous emission monitoring of NO_x, CO, particulate, TOC, HCl, HF, and SO_2 as well as semi-annual monitoring of metals and D&F. This monitoring will ensure that the emissions remain below the manufacturer's guarantee.

6.3.4 Landfill Flares

Landfill Gas emissions from the capped section of GTLF are currently collected and directed to 5 landfill flares. The combustion of LFG in these flares reduce the Greenhouse Gas impacts on the environment. The flares will be de-commissioned when the proposed enclosed Landfill Gas Flare System becomes operational. when the Project is commissioned. To be conservative, the emissions from these flares are included in the maximum future emissions assessment to allow for the potential overlap in EFW stack emissions in addition to the landfill flares. Details of the flares, along with its emission estimates are provided in Table 5.

6.3.5 Landfill Gas Flare

A dedicated enclosed Landfill Gas Flare system is proposed to flare excess landfill gas during the operational phase of the Project. The Landfill Gas Flare can handle a maximum flowrate of 500 Nm^3/hr. Details of this flare, along with its emission estimates are provided in Table 6.

6.3.6 Medical Waste Incinerator

An existing medial waste incinerator (MWI) was included in the background NOx emissions assessment, discussed in Appendix C. The incinerator processes about 6,400 pounds of waste in one batch and the burn and cooldown cycle lasts about 24 hours. The site operates 2 batches per week to process the current inflow of medical waste. The Project will include a replacement of the existing Medical Waste Incinerator, in kind. Emissions information for current MWI is not available nor is info on operational practices. The operations of the MWI under the operation of the Project will follow standard protocols. The emissions from this source will be relocated with a new exhaust stack towards the northern to the eastern section of the Site. See Table C.5 for details of the emission estimate and source parameters.

6.3.7 Haul Road within ISWMS

Currently, the road to unload material at the existing facility is predominantly unpaved. A paved haul road will be constructed from the ISWMS entrance to the ERF to facilitate movement of traffic. Paving the onsite roads will significantly reduce potential emissions from the road as a source. The formula 13.2.1.3 (2) from AP-42 was used to estimate the road particulate emissions. This formula takes into account the number of days in a year that had rain, since the resuspension of particulates on a rainy day would be negligible. A rain day is defined to be any day with at least 0.01 inches of rain, and this information was sources from “The Cayman Islands’ Compendium of Statistics 2021”. The ISWMS Facility plans on implementing a fugitive dust management program that will be outlined in the EMP to control particulate emissions from the haul roads. Details of the emissions factor and parameters used for estimating emission rates are mentioned under Table 7.

7. Dispersion Modelling

This section provides a description of how the dispersion modelling was conducted for the Project to calculate the maximum concentration at a point of impact, and for comparison to the monitored background concentrations. The Assessment for this Project was carried out using AERMOD, one of the United States Environmental Protection Agency’s (USEPA) preferred and recommended atmospheric dispersion models. The AERMOD modelling system includes the Plume Rise Model Enhancements (PRIME) algorithms for assessing the effects of buildings on air dispersion.

The AERMOD modelling system is made up of the AERMOD dispersion model, the AERMET meteorological pre-processor and the AERMAP terrain pre-processor. The following dispersion model and pre-processors were used in the assessment:

– AERMOD dispersion model (v. 22112)
– AERMAP surface pre-processor (v. 18081)
– BPIP building downwash pre-processor (v. 04274)

A summary of the AERMOD source input parameters is provided in Appendix F.

Same structure contamination was not considered. General building vents, roof exhausts, building heating, ventilation, and air conditioning were considered as negligible sources and not considered as a part of this modelling Assessment.

7.1 Co-ordinate System

The Universal Transverse Mercator (UTM) coordinate system was used to specify model object sources, buildings, and receptors. All coordinates were defined in the North American Datum of 1983 (NAD83), zone 17 north.

7.2 Meteorology

7.2.1 Meteorological Records

The Owen Roberts International Airport is the nearest meteorological station with available hourly meteorological data. Data for this station was retrieved from the US National Oceanic and Atmospheric Administration (NOAA) Integrated Surface Database (ISD; also referred to as theTD-3505 ISHD full archival format) for review. The Owen Roberts station is identified as ID 783840-11813 in the ISD. Data from 2011 to 2020 was retrieved and reviewed.

Review of the Owen Roberts station data indicated that the ISD data was incomplete since approximately 35% of total records were missing. Nighttime-hours represented the majority of the missing-hours, typically the eight-hour span between 10 PM and 6 AM. Nighttime-hours typically have cooler conditions resulting in more calm and low wind conditions.

Some data elements were also determined to be missing from otherwise complete hourly records. These missing elements varied randomly and at different rates. Missing elements included: wind speed, wind direction, temperature, humidity, pressure, cloud cover and precipitation.

As a result of the review, the ISD data was not used. A wind rose plot of the Owen Roberts station data is provided as Figure 5.

7.2.2 Prognostic Meteorological Data

Due to the incompleteness of the Owen Roberts data, prognostic meteorological data was used instead. AERMET-ready data was acquired from Lakes Environmental Software. The simulation data was produce using the Weather Research and Forecasting (WRF) model and further processed using the USEPA Mesoscale Model Interface Program (MMIF) for use with the AERMET meteorological preprocessor (surface .DAT and upper air .FSL files). The prognostic WRF data was generated with the following parameters:

– Center Point: Latitude, 19.311 N; Longitude, 81.374 W
– WRF Grid Cell: 4 km x 4 km
– Start/End Data: January 1, 2017 hour 00 to December 31, 2021 hour 23
– Datum: WGS 84
– UTM Zone: 17

A wind rose of the Prognostic data is provided in Figure 6. A comparison of Figures 5 and 6 shows similar distributions of wind directions and wind speeds. The Prognostic data set is a therefore a reasonable data set to use for this Assessment.

7.2.3 Land Use Preprocessing

Land use was extracted from the Global Land Cover Characterization (GLCC) dataset for use in calculating the surface characteristics (albedo, Bowen ratio, surface roughness) surrounding the facility using AERSURFACE v.20060. Surface characteristics were calculated on a monthly basis and for the maximum number of wind sectors. The AERMET output surface characteristics are tabulated in Appendix G.

7.2.4 AERMET Processing

The prognostic data was processed using AERMET v.22112 into AERMOD-ready surface (.SFC) and profile (.PFL) files.

7.3 Terrain

AERMOD captures the essential physics of dispersion in complex terrain though the use of a separate height scale factor for each receptor (USEPA, 1998 – AERMAP UG). The highest scale factor represents the terrain that would dominate flow in the vicinity of the receptor. The height scale factor that is used by AERMOD is generated by an AERMAP terrain pre-processor. AERMAP utilizes terrain data, or Digital Elevation Model (DEM) data in conjunction with a layout of receptors and sources to generate height scale factors that can be directly used in AERMOD. Terrain data used in this assessment was obtained from United States Geological Survey's Shuttle Radar Topography Mission (SRTM) 1 Arc-Second (~30m) Global data.

7.4 Receptors

For this Assessment two sets of receptor grids were used. One set for the simulation of background concentrations using existing emissions sources, and the second set for determining the maximum concentrations from the full-time operation of the Project.

For the modelling of background concentrations, a 5 km x 5 km uniform grid was used, with a uniform spacing of 500 m between each receptor. Uniform polar grid (5 rings with increments of 20 m, with 36 direction radials in increments of 10 degrees) receptors were also placed at the location of the background air monitoring stations. At the Site's property line, ground level receptors with a 20 m spacing was used to evaluate the maximum property boundary concentrations. No receptors were placed within the Site's property line.

The background concentrations modelling grid is provided in Appendix F. Figure F.1 shows the receptors used for modelling background concentrations.

For the determination of maximum concentrations due to emissions from the Site, a tiered receptor grid was defined starting with a rectangular boundary that encloses all the modelled sources (bounding box). A tiered grid was then defined starting from the edge of the bounding box with a fine resolution, to coarser resolutions further away. All tiered distances were defined relative to the bounding box. The receptor grid used is described as follows:

– 20 m spacing within 200 m of the edge of the bounding box
– 50 m spacing from 200 to 500 m
– 100 m spacing from 500 to 1,000 m
– 200 m spacing from 1,000 to 2,000 m
– 500 m spacing from 2,000 to 5,000 m
– 1000 m spacing from 5,000 m to 10, 000 m

Although the above tiered receptor grid would capture impacts at the sensitive receptors identified under Section 4.1.3, additional uniform polar grid receptors (5 rings with increments of 20 m, with 36 direction radials in increments of 10 degrees) were placed at all these sensitive receptors, except for the seven mile beach corridor. The above mentioned tiered receptor grid should sufficiently capture impacts along the seven-mile beach corridor.

The maximum concentrations modelling grid is provided in Appendix F. Figure F.2 and Figure F.3 shows the receptors used for modelling maximum concentrations.

7.5 Building Downwash

The Facility buildings were entered into the model using the USEPA Building Profile Input Program (BPIP-PRIME). The inputs into this pre-processor include the co-ordinates and heights of the buildings and stacks. The BPIP program

was executed to evaluate any building cavity downwash effects. Cavity downwash can result in air contaminants being forced to ground level prematurely under certain meteorological conditions. The on-site buildings and structures were modelled with their respective average roof heights.

The PRIME plume rise algorithms include vertical wind shear calculations (important for buoyant releases from short stacks (i.e., stacks at release heights within the recirculation zones of the buildings). The PRIME algorithm also allows for the wind speed deficit factors to improve the accuracy of predicted concentrations within building wake zones that form in the lee of buildings.

The layout of the ISWMS facility used for the purpose of this Assessment is provided in Appendix D.

7.6 Deposition

AERMOD has the ability to account for wet and dry deposition of substances that would reduce ground level concentrations at points of impact. However, the deposition algorithm has not been implemented in this assessment and therefore, the predicted concentrations are considered to be more conservative.

7.7 Averaging Time and Conversions

The shortest time scale that AERMOD predicts is a 1-hour average value. Many of the standards are based on 1-hour, 24-hour, and annual averaging times, which are averaging times that can also be calculated by AERMOD. In cases where a standard has an averaging period less than 1-hour (e.g., 10-minute), a conversion to the appropriate averaging period was completed using the Ontario's Ministry of the Environment, Conservation and Parks recommended conversion factors, as documented in the Air Dispersion Modelling Guideline for Ontario (Guideline A-11) Version 3.0.

8. Modelling Results and Discussion

The estimated emissions for background sources of NO_x and the estimated Project emissions, as described in Section 4 and Section 5, were used in the AERMOD modelling, as described in Section 6. This Section provides a discussion of the results of the background NO_x modelling and the future Project emissions modelling. The existing background NO_x emissions model results are compared with the background monitoring results for NO_x. The future Project model results, including the addition of the background air contaminant concentrations, are compared with the air quality standards listed in Table 1.

8.1 Background Emissions

The modelled 90th percentile NO_x (as NO_2) results were compared to the measured background monitoring values. A summary of which is shown in Table 8. The modelled 90th percentile results are consistent with the measured values at each monitoring station.

8.2 Project Operation

The modelled maximum off-site contaminant concentrations from the Project were added to the measured background concentration (Table 3) for each air contaminant to obtain the cumulative impact. The off-site concentrations from the Project are conservatively based on the highest modelled values for the maximum potential emission rates. The data was not refined to remove any meteorological anomalies or to apply any statistics. The cumulative concentrations (modelled Project concentration plus background) were compared to the appropriate limits (Table 1) for compliance. A summary of the results is shown under Table 9.

All contaminants are shown to have a cumulative concentration that is below the applicable air quality standard. This shows that the implementation of the Project will not result in any air quality exceedances.

Dioxins and Furans (PCDD/PCDF)

PCDD/PCDF are expected contaminants from the ERF stack. The PCDD/PCDF concentrations were assessed with background concentrations and maximum potential emissions from the ERF stack. The Project emissions contribute up to 54% of the cumulative concentration.

There are no ambient air quality limits for dioxins and furans in the **UK National Air Quality Objectives**, therefore the air quality standard from Ontario, Canada is used instead. With the Project in full operation, the PCDD/PCDF cumulative concentration is 23% of the defined air quality standard limit.

Particulate Matter

PM_{10} and $PM_{2.5}$ are expected contaminants from the EFR stack and from the haul roads. The haul roads are located close to the Site property line and therefore the maximum cumulative concentrations of PM are observed to occur directly on the property line and contribution is dominated by the haul road emission source. The Project emissions contribute up to 61% of the daily and 38% of the annual cumulative concentrations of PM_{10}.

The cumulative concentration from the background air quality and the future project are shown to be below the **UK National Air Quality Objectives** for both the 24-hour and annual standards. The cumulative concentrations for PM_{10} are 81% of the 24-hour limit and 77% of the annual limit. The cumulative concentration for $PM_{2.5}$ is 40% of the annual limit.

Hydrogen Chloride

HCl is an expected contaminant from the ERF stack. The HCl concentrations were assessed with background concentrations and maximum potential emissions from the ERF stack. The Project emissions contribute up to 7% of the cumulative concentration. The 1-hour maximum cumulative concentration is 5% of the air quality standard limit.

Hydrogen Fluoride

HF is an expected contaminant from the ERF stack. The HF concentrations were assessed with background concentrations and maximum potential emissions from the ERF stack. The Project emissions contribute up to 1% of the hourly and less than 1% of the annual cumulative concentrations. The 1-hour maximum cumulative concentration is 14% and the annual maximum cumulative concentration is 44% of the air quality standard limit.

Sulphur Dioxide

SO_2 is an expected contaminant from the ERF stack and the future landfill gas enclosed flare. The SO_2 concentrations were assessed with background concentrations and maximum potential emissions from the Project. The Project emissions contribute up to 19% of the 15-minute, 47% of the hourly, and 40% of the daily cumulative concentrations. Of the three SO_2 air quality standard limits, the highest percent of limit that SO_2 reaches is 36% of the 15-minute limit.

Oxides of Nitrogen

NO_2 is an expected contaminant from the ERF stack, the future landfill gas enclosed flare, and the existing landfill flares. Assessment of the maximum NO_2 emissions included both the flare types to allow for overlap between the decommissioning of the existing flares and the installation of the new flare. The NO_2 concentrations were assessed with background concentrations and maximum potential emissions from the Project. The Project emissions contribute up to 70% of the hourly and 41% of the annual cumulative concentrations. The 1-hour maximum cumulative concentration is 83% and the annual cumulative concentration is 54% of the air quality standard limit.

Carbon Monoxide

CO is an expected contaminant from the ERF stack, the future landfill gas enclosed flare, and the existing landfill flares. Assessment of the maximum CO emissions included both the flare types to allow for overlap between the decommissioning of the existing flares and the installation of the new flare. The CO concentrations were assessed with background concentrations and maximum potential emissions from the Project. The Project emissions contribute

up to 13% of the cumulative concentration. The existing landfill flares are the highest contributors to this maximum concentration. This concentration is 26% of the air quality standard limit.

Heavy Metals

The CoPCs, defined in Section 2.3, includes twelve metals that may emit from the ERF activities. For the purpose of detailed monitoring and assessment, four metals were selected as the worst-case metals that have the lowest emission standards to compare against. Cadmium, arsenic, lead, and nickel are therefore assessed as the most stringent air quality standard metals.

Background monitoring for these metals showed that ambient concentrations are very low. Emissions from the ERF stack contribute between 65% to 83% of the cumulative concentration for each of these metals. Of the four metal air quality standard limits, the highest percent of limit is 86% for arsenic.

9. Conclusions

This Assessment was prepared to provide an assessment of the air quality impacts resulting from the proposed Project.

Background monitoring was conducted in the Study Area to determine site-specific background air quality data for contaminants of concern. Using emission estimates and dispersion modelling, a theoretical background emissions assessment for NO_2 was conducted and compared to the results of the NO_2 monitoring program. The calculated assessment demonstrated similar background concentrations to the measured concentrations, thereby demonstrating the reliability of the monitoring program results.

Existing air quality in the Study Area was shown to be in compliance with the applicable air quality standards with one exception of an odour-based standard for H_2S. This outlier is further explained in the odour assessment documented in the Air Monitoring Report.

The potential impacts of the proposed Project on local air quality were assessed by modelling the estimated maximum emissions of each contaminant to determine the maximum potential concentration of each contaminant that could occur off-site of the property. The cumulative air quality impacts that included the determined background concentrations were compared to relevant standards and guidelines and to the existing air quality conditions.

The results of this Assessment showed increased contaminant concentrations due to the additional emissions from the Project. The contaminants with the most significant increase are the metals due to the background monitoring not detecting significant background concentrations. All cumulative impacts are shown to be below the air quality standards. The standard values of pollutants used as reference for this assessment are protective of human health.

https://uk-air.defra.gov.uk/assets/documents/Air_Quality_Objectives_Update.pdf

(2) NO_2 not to be exceeded more than 18 times a year.

(3) PM_{10} (24 hour average) not to be exceeded more than 35 times a year.

(4) SO_2 (1 hour average) not to be exceeded more than 24 times a year.

(5) SO2 (24 hour average) not to be exceeded more than 4 times a year.

(6) SO2 (15 minute average) not to be exceeded more than 35 times a year.

(7) Reporting Standards for Hydrogen Sulphide (odour based) and Dioxins and Furans were sourced from "The Ministry of the Environment, Conservation and Parks" of Ontario, Canada.
https://www.ontario.ca/page/ontarios-ambient-air-quality-criteria#section-4

(8) These contaminants were measured for the background air quality assessment, however are not included in the Project modelling due to the Project not being expected to emit these contaminants.

(9) CoPCs were defined in the Terms of Reference and Air Quality Method Statement. Total dust is assessed using Particulates (PM_{10} and $PM_{2.5}$). VOCs and TOCs represent a grouping of substances and does not have applicable air quality standards to list in this table.

(10) The UK AAD Limit value for PM2.5 was updated in 2020 from 25 $\mu g/m^3$ to 20 $\mu g/m^3$. Therefore, the updated value was used as it is more conservative than the limit defined in the terms of reference.

Volatile Organic Compounds 1 Hour Background Concentrations								
VOCs (Benzene)	1	COX Lumber	71-43-2	1 Hour	$\mu g/m^3$	**1.587**	**30**	**5%**
Hydrogen Sulphide 10 Min Background Concentrations								
Hydrogen Sulphide	5	Lakeside	7783-06-4	10 Min	$\mu g/m^3$	**34.847**	**13**	**268%**
Hydrogen Sulphide	7	Laundry	7783-06-4	10 Min	$\mu g/m^3$	2.788	13	21%
Dioxin and Furans 24 Hour Background Concentrations								
Mid Point PCDD/F TEQ (WHO 2005)	1	COX Lumber	-	24	$pgTEQ/m^3$	**0.013**	**0.1**	**13%**

Notes:

(1) For the various parameters and their averaging periods (except for the annual averaging period), the 90th percentile value was used to represent the background concentration.
(2) For the various parameters for which the annual averaging period is applicable, the average of the entire sampling duration was used.
(3) PCDD/F - Polychlorinated Dibenzo-p-dioxins (PCDDs, Dioxins) and Polychlorinated Dibenzofurans (PCDFs, Furans),
(4) TEQ - Toxic equivalency of a dioxin or furan homologue to that of 2,3,7,8 PCDD.
(5) The background concentrations that are in BOLD font for each parameter, are the maximum from all the monitored stations.

Table 4

Estimated Pollutant Emission Rates
Main Stack at ERF

Pollutant	Emission Limit Values [4] (mg/Nm^3)	Gas Concentration [8] STP-Dry (mg/Nm^3)	Emission Rate (g/s)
SOx	50	50	6.54E-01

Stack Parameters

Stack UTM X Coordinate (m)	Stack UTM Y Coordinate (m)	Exhaust Flow rate (m^3/s)	Gas Exit Temperature (°C)	Stack Tip Inside Diameter (m)	Stack Tip Release Height (m above msl)
460836.68	2134829.23	24.982	141	1.3	44.58

Notes:

(1) Stack parameters and stack emissions were communicated by METKA, through their email on August 8, 2022. The stack concentration of Cd and Tl together is 0.05 (mg/Nm^3), but was conservatively assumed to be 0.05 (mg/Nm^3) each. Similarly the stack concentration of Sb, As, Pb, Cr, Co, Cu, Mn, Ni, and V together is 0.5 (mg/Nm3), but was conservatively assumed to be 0.5 (mg/Nm^3) each.
(2) Exhaust volumetric flow rate is 47,108 m^3/hr STP-Dry.
(3) As communicated by Iona Capital Ltd. in their email on December 23, 2022; the actual stack height is designed to be 41.23 m, but after grading and construction, the Stack Tip Release height is designed to be at 44.58 m above mean sea level. The Stack Tip Release height was adjusted in the dispersion model, such that it represented 44.58 m above mean sea level.
(4) Directive 2010/75/EU of the European Parliament and of the Council of 24 November 2010 on industrial emissions (integrated pollution prevention and control).
(5) In-stack limit only. Not included in dispersion modelling. See Report text for discussion.
(6) Half-hour average value selected to conservatively assess CO emissions against 8 hour average air standard
(7) Although the emission limit value for Arsenic is a cumulative limit for the group of heavy metals, the manufacturer has provided that measurements from other plants have shown arsenic concentrations well below 0.1 mg/m^3
(8) Some concentrations limited by the BAT conclusions (WI-BREF 2019) - See Appendix C.

Table 5

Estimated Emission Rates - Passive Vent Flares on the Landfill

Make and Model of Passive Vent Flare	Landfill Gas Flow Rate per Vent(Nm^3/hr)	NOx Emission Factor (kg/10^6m3 methane) [1]	CO Emission Factor (kg/10^6m3 methane) [1]	NOx Emission Rate [2] (g/s)	CO Emission Rate [2] (g/s)
Solar Spark Flare CF-5	153	650	1.20E+04	0.015	0.281

Stack Parameters

Source ID	Stack UTM X Coordinate (m)	Stack UTM Y Coordinate (m)	Gas Exit Flow rate [3] (m^3/s)	Gas Exit Temperature [4] (°C)	Stack Tip Inside Diameter (m)	Effective Release Height (m)
FLARE1	460726.97	2135220.77	0.043	350	0.038	3.626

FLARE5	460807.44	2135183.22	0.043	350	0.038	3.626

Notes:

(1) Emission factors used as provided by USEPA AP-42 in Chapter 2.4, Table 2.4.2 (1998) for landfill gas flares as these are the factors with the highest data quality available.
(2) The emission rates have been determined based on an estimated 55% methane in biogas
(3) A reasonably conservative assumption of maximum design flow rate was used.
(4) A typical open flare specification can range from 350-950° C. The lowest temperature of 350°C is used as the conservative value.

Table 6

Estimated Emission Rates - Landfill Gas Flare

Maximum Biogas Flow Rate **500** Nm^3/hr

Compound	CAS No.	Emission Factor (kg/10^6m^3 methane) (1)	Concentration in Biogas mg/Nm^3	Estimated Maximum Emission Rate for Flare (S3) (g/s) (2)

Notes:
(1) Emission factors used as provided by USEPA AP-42 in Chapter 2.4, Table 2.4.2 (1998) for landfill gas flares as these are the factors with the highest data quality available.
(2) The emission rates have been determined based on an estimated 55% methane in biogas
(3) The concentration of SO_2 is based on the 50 mg/Nm^3 SOx emission limit from Directive 2010/75/EU of the European Parliament and of the Council of 24 November 2010 on industrial emissions (integrated pollution prevention and control).

Table 7

Estimated Particulate Emission Rates - Future Paved Haul Route within ISWMS

Variable or Constant	$PM_{2.5}$	PM_{10}
k (g/VKT)	1.1	4.6
sL (Silt Loading)[1]	0.33	0.33

Formula (AP-42 13.2.1.3 (2)):
EF(g/VKT) = [k * (sL)^0.91 * (W)^1.02] *(1-P/4N) * (100% - CE)
Where P = 138 (number of days in a year with at least 0.254 mm (0.01 in) of precipitation.)
N = 365 days in a year
CE = 50% Control Efficiency

		Emission Factors	
Truck Route	**W - Mean Vehicle Weight of Haul Truck (ton)**	**PM_{10} (g/VKT)**	**$PM_{2.5}$ (g/VKT)**
ISWMS			
Entrance->Tipping Face	13	1.05E+01	2.50E+00

Estimated Particulate Emission Rates - Haul Route within ISWMS
ER(g/s) = EF(g/VKT) * # of trips * Distance (km) / (3600 s/hr)

Distance from Entrance to Tipping Face (km) = 0.61

		Hourly Emission Rates	
Truck Route	**# of One-way Trips per hour**	**PM_{10} (g/s)**	**$PM_{2.5}$ (g/s)**
ISWMS			
Entrance->Tipping Face	26	4.59E-02	1.10E-02

Notes:

(1) The paved road surface silt loadings from Site C of Reference 31 and Commercial/Industrial roads of Reference 8 from Emission Factor Documentation for Ap-42 Section 13.2.1 (January, 2011) were averaged to get a representative silt loading for this Facility.
https://www.epa.gov/sites/default/files/2020-10/documents/emission_factor_documentation_for_ap-42_section_13.2.1_paved_roads_.pdf
(2) Tailpipe particulate emissions have not been included as they are insignificant when compared to road dust emissions.
(3) The Mean Vehicle Weight was estimated using a weighted average of the truck traffic data for the month of October in the year 2022.
(4) The number of rain days data was obtained from "The Cayman Islands' Compendium of Statistics 2021". The average number of rain days from the years 2017 through 2021 was used.
(5) According to the State of Utah Department of Environmental Quality Guidelines memo (January 12, 2015), a control efficiency of 95% can be achieved through vacuum sweeping and watering of paved roads.
https://documents.deq.utah.gov/air-quality/permitting/operating-permits/DAQ-2015-020242.pdf

Table 8

Measured and Modelled NO_2 Background Concentrations (1 hour averaging)

					Modelled Concentrations by Source Group [1]					
Station #	**Station Name**	**Units**	**Measured Background Concentration (90th Percentile)**	**Modelled Background Concentration (90th Percentile) [1]**	**Roads**	**Airport**	**Port**	**CUC**	**Hot Mix Asphalt & Concrete Batch Mixers**	**Small Boilers**

Air Quality Method Statement

Technical Memorandum

September 07, 2021

To	Richard McAree (Dart), Martin Edelenbos (Dart)	**Tel**	519-884-0510
Copy to	Blair Shoniker, GHD	**Email**	gordon.reusing@ghd.com/ john.macrae@ghd.com
From	Gordon Reusing/John MacRae	**Ref. No.**	12500295-MEM-1
Subject	Revised Air Quality Method Statement		

1. Introduction

This Revised Air Quality Method Statement (Method Statement) describes the baseline monitoring of ambient air quality (Monitoring) that will occur in the local area of the George Town Landfill (GTLF) on Grand Cayman Island (Cayman) to support an Environmental Impact Assessment (EIA) for the proposed Integrated Solid Waste Management System (ISWMS).

The Method Statement is intended to address the **Responses to Comments - Review of the Integrated Solid Waste Management System for the Cayman Islands: Environmental Impact Assessment Final Draft Terms of Reference provided on 4 March 2021,** specifically with respect to Section 5: Air Quality. The Method Statement addresses the following comments:

– The locations of monitoring.
– The duration of monitoring.
– The key pollutants which will be monitored.
– The seasonality of the monitoring duration.
– Comprehensive and representative of baseline conditions.
– Current sources of key pollutants.
– Additional comments were received on August 26, 2021 from the Environmental Assessment Board (EAB) and their consultants, which have been considered in this revised Air Quality Method Statement.

1.1 Objective

The objective of the Monitoring will be to accurately measure the baseline concentrations of air contaminants in the area to determine existing conditions in support of the EIA for the ISWMS that will incorporate the following potential air emission sources:

– An Energy Recovery Facility (ERF) for the treatment of Municipal Solid Waste (MSW)

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

– A Green Waste Facility for outdoor processing (composting and mulching) of organic waste
– An End-of-Life Vehicle (ELV) and Scrap Metal Processing Facility
– A Construction and Demolition (C&D) Waste Facility
– A Bottom Ash Processing Facility
– A Medical Waste Processing Facility
– A Landfill Gas Facility
– A Residual Waste Landfill

Baseline air monitoring is necessary since air quality monitoring is not routinely undertaken on the Cayman Islands, and no data is publicly available on existing levels of air pollutants. The monitoring data will be used in conjunction with predictive dispersion modelling using the AERMOD dispersion model to determine the cumulative effects of the ISWMS.

2. Guidance

Cayman Islands is an overseas British Territory. Air quality guidance will therefore be referenced from the current EU Directives as noted in Table 5.30 of the ToR.

2.1 EU Industrial Emissions Directive (IED – 2010/75/EU)

As stated in the ToR, emissions in the Cayman Islands are guided by the **EU Industrial Emissions Directive (IED – 2010/75/EU)** which stipulates acceptable emission values to atmosphere for industry including waste incineration processes such as the ERF.

Chapter IV of the IED entitled **Special Provisions for Waste Incineration Plant and Waste Co-Incineration Plants** sets forth the guidance through which the emissions into air from waste incineration and waste co-incineration are to be monitored and the emission limit values that the monitored emissions shall not exceed. Based on Chapter IV, reference is made to Annex VI, Parts 3 and 4 that describe the parameters that should be monitored continuously and non-continuously from the emissions of these types of facilities. These parameters are as follows:

– Dioxins and Furans
– Total Dust
– Gaseous and vaporous organic substances (VOC) as Total Organic Carbon (TOC)
– Hydrogen Chloride (HCl)
– Hydrogen Fluoride (HF)
– Sulphur Dioxide (SO_2)
– Oxides of Nitrogen (NOx) expressed as NO_2
– Carbon Monoxide (CO)
– Heavy Metals:
    - Cadmium (Cd)
    - Thallium (Tl)
    - Mercury (Hg)
    - Antimony (Sb)
    - Arsenic (As)
    - Lead (Pb)
    - Chromium (Cr)

- Cobalt (Co)
- Copper (Cu)
- Manganese (Mn)
- Nickel (Ni)
- Vanadium (V)

Baseline monitoring should therefore include these compounds that will be attributable to the future ERF as well as local air emission sources.

2.2 Ambient Air Sampling Methods

The European Commission, acting through the European Committee for Standardisation (CEN) has produced a series of Standard Methods for monitoring air pollutants. These documents outline minimum performance requirements for analyzers, to ensure that measurement methods comply with the Data Quality Objectives (DQO) set down in the **Ambient Air Quality Directive (2008/50/EC)** and in the amending **Directive (EU) 2015/1480**. The current versions of these standards are listed below:

– EN14211:2012 Nitrogen Oxides
– EN14212:2012 Sulphur Dioxide
– EN14626:2012 Carbon Monoxide
– EN12341:2014 PM_{10} and $PM_{2.5}$
(EN16450:2017 Automatic PM analyzers)
– EN14662-1:2005 and 14662-3:2015 Benzene
– EN 14902:2005 'Standard method for measurement of Pb/Cd/As/Ni in the PM10 fraction of suspended particulate matter

The baseline monitoring will follow these standards.

2.2.1 UK Type Approval of Gaseous Analyzers: MCERTS

For gaseous analyzers, the Type Approval testing process is managed in the UK by the Environment Agency under its MCERTS scheme with certification provided by SIRA the appointed certification body. The MCERTS Performance Standards mirror the requirements of the CEN Standard Methods. The relevant performance standard for gases is: **MCERTS: Performance Standard for Continuous Ambient Air Quality Monitoring Systems**. This standard will be followed with regard to the Quality Assurance and Quality Control (QA/QC) of the continuous monitoring data.

2.2.2 UK Deployed Monitoring Methods

The techniques used for monitoring within the UK's national compliance monitoring network, the Automatic Urban and Rural Network (AURN) are summarized below. Except for the automatic PM10 analyzers, the reference methods of measurement are defined in the relevant EU Directives.

Based on this guidance the ambient air monitoring methods that will be used for the continuous monitoring of gaseous pollutants, and the methods that will be considered for continuous monitoring of dust (PM10 and PM2.5) will be as follows:

NO/NO_2	Chemiluminescence
SO_2	UV fluorescence
CO	IR Absorption

PM_{10} and $PM_{2.5}$	• Tapered Element Oscillating Microbalance • Beta Attenuation Monitor • Gravimetric Monitor • Filter Dynamics Measurement System (FDMS) • Optical Light Scattering • Fine Dust Analysis System (FIDAS)

2.3 Non-Continuous Methods

Since the Cayman Islands are located closer to the US and Canada than the UK, consideration needs to be given to the ways in which non-continuous samples that require external laboratory analysis are handled. Laboratories in the US and Canada are not normally accredited for EN or UK analytical approaches although they are essentially the same in most cases. Therefore, for the non-continuous methods that require laboratory analysis of samples, this program will utilize equivalent ambient air methods with analyses that are normally completed in North America due to hold times of samples. As such the following approaches for the non-continuous samples are based on North American references and methodologies. All ambient air samples will be analyzed by environmental laboratories that are accredited in the analysis of environmental air samples, namely, ALS Laboratory Group and Bureau Veritas.

2.3.1 Dust and Metals

Dust (PM10) and metals in the PM10 fraction will be determined by United States Environmental Protection Agency (USEPA) **Method IO-2.1 Sampling of Ambient Air for Total Suspended Particulate Matter (SPM) and PM10 Using High Volume (HV) Sampler**. Metals noted in Section 2.1 will be analyzed by **USEPA Method IO-3.5 Determination of Metals in Ambient Particulate Matter Using Inductively Coupled Plasma/Mass Spectrometry (ICP/MS).** Samples will be collected every 6 days for the baseline monitoring duration based on the North American schedule.

2.3.2 Hydrogen Chloride

A non-continuous method for measurement of acid gases is provided in the USEPA **Method OTM-40** that uses sorbent traps to collect acid gases with subsequent analysis by Ion Chromatography (IC). This approach will be modified to collect HCl and HF in ambient air for this project.

2.3.3 Dioxins and Furans and Polycyclic Aromatic Hydrocarbons (PAH)

A non-continuous method for measurement of dioxins and furans in ambient air is provided in the USEPA **Compendium of Methods for the Determination of Toxic Organic Compounds in Ambient Air: Method TO-9A Determination of Polychlorinated, Polybrominated and Brominated/Chlorinated Dibenzo-p-Dioxins and Dibenzofurans in Ambient Air.** This non-continuous method uses a polyurethane foam plug or XAD-2 to capture dioxins and furans using a medium volume sampler. Laboratory analysis is by High Resolution Mass Spectroscopy (HR/MS). PAH can also be analyzed from the XAD-2 if required. Samples will be collected every 6 days for the baseline monitoring duration based on the North American schedule.

2.3.4 VOC and TOC

A non-continuous method for measurement of VOCs in ambient air is provided in the USEPA **Compendium of Methods for the Determination of Toxic Organic Compounds in Ambient Air: Method TO-15 Determination of Volatile Organic Compounds (VOCs) in Air Collected in Specially Prepared Canisters and Analyzed by Gas Chromatography/Mass Spectrometry (GC/MS)**. This non-continuous method uses evacuated canisters to collect VOCs in ambient air and analyzes a specific list (TO-15) of toxic organic VOCs. TOC will be calculated as the total of the VOCs detected and reported as toluene.

VOC samples may also be analyzed for methane and other compounds associated with landfill odours. Samples will be collected every 6 days for the baseline monitoring duration based on the North American schedule.

2.3.5 Applicable Air Quality Standards and Averaging Periods

A summary table has been provided to detail the applicable air quality standards and averaging periods to which the baseline measurements will be compared. The summary is provided in Table 1. The values in Table 1 are the UK National Air Quality Standards.

2.4 Other Air Notable Air Contaminants Existing Conditions

Odour and bioaerosols l are assessed to determine existing conditions of the GTLF and local surrounding areas. Landfilling of organic wastes will significantly decrease after the ISWMA is operational, therefore odour is expected to decrease.

2.4.1 Odour Assessment

The assessment of odour for planning purposes is guided in the UK by the document entitled, **Guidance on the Assessment of Odour for Planning** (Institute of Air Quality Management July, 2018).

As per Section 3 of this document, the existing conditions of sources of odour will be determined as follows:

1. A description of existing baseline odour conditions (including complaints history if available).
2. A description of the location of receptors and their relative sensitivities to odour effects.
3. Details of potential odour sources (whether existing or proposed), including the activities and materials involved (including a brief outline of quantities, durations, methods of handling and storage, etc) and the resulting potential for generating odours, covering fugitive sources, diffuse sources and point sources as applicable.
4. A description of control/mitigation measures incorporated into the scheme (including management controls and, where appropriate, engineering controls).
5. A prediction or observation (or combination of both), using appropriate assessment tools, of the likely odour impact and resulting effects at relevant sensitive receptors, and taking into account:
    a. The likely magnitude of odour emissions (after control by measures incorporated into the scheme, if applicable).
    b. The meteorological characteristics at the site.
    c. The dispersion and dilution afforded by the pathway to the receptors and the resulting magnitude of odour that could result.
    d. The sensitivity of the receptors.
    e. The potential cumulative odour effects with any odours of a similar character.

Odour assessment surveys are guided by EN 264086 Parts 1 and 2. A combination of odour assessment tools will be used for determining the existing conditions as follows:

1. Sensory Assessment using field olfactometry (Nasal Ranger™ or equivalent) to measure the concentrations of existing landfill odours including all upwind sources (mangroves and WWTP) and all onsite sources including all processes currently in use.
2. Compound analysis of existing upwind and downwind H2S readings from the gold-film analyzers.

The measured odour values of point and area sources along with the inferred odour concentrations from collected H2S data will be used to determine existing conditions of odour as well as performing dispersion modelling using the AERMOD dispersion model to predict current odour concentrations at the sensitive receptors.

2.4.2 Bioaerosols

Bioaerosols were considered as part of the determination of existing conditions for the project. In consideration of the potential effect of bioaerosols at sensitive receptors the following UK guidance documents were referenced:

- **Technical Guidance Note (Monitoring) M9 Environmental Monitoring of Bioaerosols at Regulated Facilities, Environmental Agency, July 2018**
- **Occupational and Environmental Exposure to Bioaerosols from Composts and Potential Health Effects - A Critical Review of Published Data, 2003**
- **Guidance on the Evaluation of Bioaerosol Risk Assessments for Composting Facilities; Leeds University, 2008**
- **Site Specific Bioaerosol Risk Assessment, WRM, 2020**

Bioaerosols are found naturally within the environment. They consist of airborne particles that contain living organisms, such as bacteria, fungi and viruses or parts of living organisms, such as plant pollen, spores and endotoxins from bacterial cells or mycotoxins from fungi. The components of a bioaerosol range in size from around 0.02 to 100 micrometres (μm) in diameter. The size, density and shape of a bioaerosol will affect its behaviour, survivability and ultimately its dispersion in the atmosphere.

Composting and anerobic digestion appear to be the largest sources of bioaerosols. The dependence on microorganisms to degrade the organic material, and the way in which the material is processed make biological treatment facilities a source of bioaerosols.

Bioaerosols degrade and disperse in the air a short distance away from the source. This distance appears to be within 200 to 250m depending on the meteorological conditions. Because of the nature of bioaerosols, their impact is largely on the workers who are exposed to them daily at close proximity and therefore can be a worker exposure issue.

The UK Environment Agency's policy position on composting and potential health effects from bioaerosols (2007) is that they will:

> "take into account the potential effects of bioaerosols on human health when authorizing new waste composting facilities or changes to existing facilities. To do this, applicants will have to provide us with a site-specific bioaerosol risk assessment if there is a workplace or dwelling within 250 metres of the composting site boundary. The assessment must be based on clear scientific evidence and show that bioaerosols can and will be maintained at appropriate levels at any workplace or boundary of a dwelling"

Dispersion models can accurately predict the movement of dusts and aerosols on which bioaerosols are attached, but cannot accurately predict efficacy, so the 250 m buffer is used.

Neither composting nor anerobic digestion are currently occurring at the GTLF. Composting of green waste will be a component of the proposed ISWMS which will be well within a 250 m buffer separating the nearest sensitive receptors. The ISWMS facility will conform to a Code of Good Practice to adopt operations and mitigation measures to control activities that may generate and affect the release of bioaerosols.

Therefore. an assessment of the existing conditions of bioaerosols will not be undertaken as part of the EIA. The ISWMS will be designed such that the potential health affects to workers and sensitive receptors will be well within UK Guidance, and a risk assessment will not be necessary.

3. Local Sources of Emissions

The existing sources of local emissions in the area of the proposed ISWMS and their primary emissions constituents are identified in Figure 1 and described further below:

- Esterley Tibbetts Highway (NOx, CO, PM2.5)

- GTLF (dust, methane (CH_4), hydrogen sulphide (H_2S), CO_2, metals from car dismantling)
- Wastewater Treatment Plant (Total Reduced Sulphur (TRS), H_2S)
- Current Medical Waste Incinerator at GTLF (emissions profile similar to the proposed ERF in Section 2.1)
- Asphalt Plant (NOx, SO_2, CO, CO_2, dust, PAH)
- Cement, Concrete and Concrete Batching Plants (NOx, SO_2, CO, CO_2, dust)
- Cayman Spirits Company (Ethanol)
- Caribbean Utilities Power Plant (NOx, SO_2, CO, CO_2, PM2.5)
- New Airport Connector Road Construction (dust, metals)

3.1 Meteorology

GHD created a wind rose with data from 2011 to 2020 from the Owen Roberts International Airport located in George Town, Grand Cayman. The data shows that the prevailing wind directions are well defined and are almost exclusively blowing in an east to west direction with slight deviations. It should be noted that the data is only 65.1% complete as the monitor doesn't appear to record anything for about 6 hours every morning (4-10 am). Additionally, the radiosonde data contains between 50-95% of the data, so some years are more complete than others.

This wind rose is provided in Figure 2.

3.2 Current Air Monitoring Data

Monitoring for H_2S using Jerome H_2S analyzers (Gold-film) is currently being undertaken on and around the GTLF. This data collection will continue during the proposed baseline air monitoring program to quantify baseline concentrations of H_2S upwind and downwind of the proposed facility.

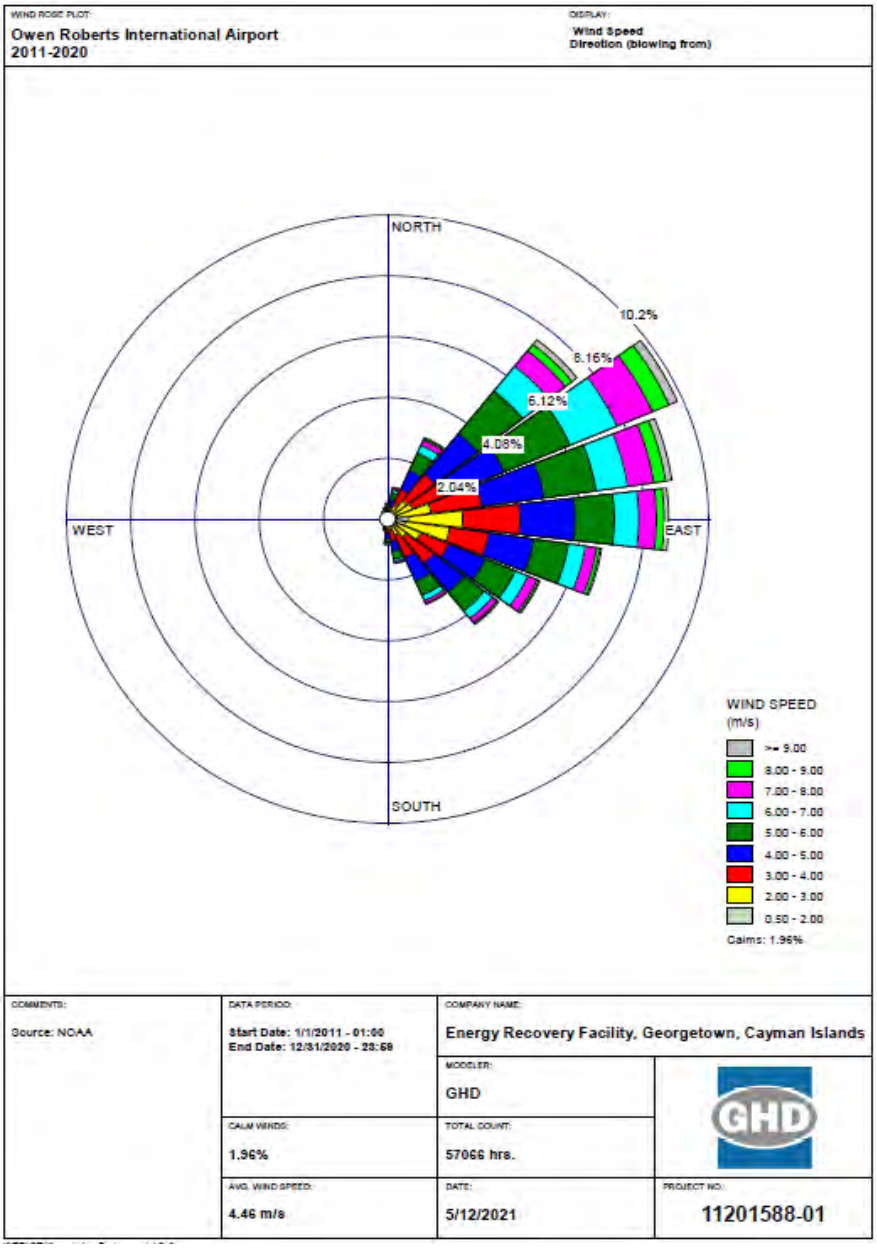

Figure 2 **Windrose**

4. Baseline Monitoring Station Locations

As per the UK Department of Environment, Food and Rural Affairs (DEFRA) at https://uk-air.defra.gov.uk/networks/site-types, a background monitoring station should be located as follows:

> *Located such that its pollution level is not influenced significantly by any single source or street, but rather by the integrated contribution from all sources upwind of the station e.g., by all traffic, combustion sources etc. upwind of the station in a city, or by all upwind source areas (cities, industrial areas) in a rural area. These sampling points shall, generally, be representative for several square kilometres.*

Based on this guidance the baseline monitoring station will be located downwind of the proposed ISWMS facility, but also downwind of other significant sources of emissions including the all the emissions sources noted in Section 3. Other siting criteria such as distance from trees, distance from major roads, absence of

building downwash effects, probe siting criteria and probe materials will be adhered to according to the Guidance. Monitoring station siting consideration will also include suitable and available spaces with power.

An upwind monitoring station is normally located as a background reference for comparison with the data collected at the downwind station. The purpose of the upwind station is to subtract any upwind concentrations of contaminants collected in the downwind station. This station would normally be located upwind of the proposed ISWMS and major sources of emissions as noted in Section 3.

However, a station located upwind of the ISWMS is not likely to be impacted by any of the emissions sources noted in Section 3, based on the 10-year wind rose provided since it will be located very close to the shoreline and winds are not predicted to blow from the direction of the industrial sections of George Town to this location. The only likely emissions sources upwind of the ISWMS could be H_2S from the mangrove swamps and the temporary emissions from construction of the new Airport Connector Road (dust).

GHD is therefore proposing a single fully instrumented monitoring station (Station 1) downwind of the ISWMS to measure baseline air quality for this project. The values measured at this station will be conservative, since no upwind values will be subtracted from the values measured at this location.

H_2S is currently being monitored around the landfill as noted in Section 3.2 and this will carry on throughout the baseline monitoring duration including locations upwind of the ISWMS. H_2S will therefore be the only parameter monitored upwind of the proposed ISWMS.

4.1 Additional Sampling for Local Sources and Sensitive Receptors

The single station ambient Monitoring program described above will provide a measure of the baseline concentrations of target pollutants in the vicinity of the project impact area and based on the windrose, will also encompass all the of the existing industrial emissions sources. There are individual existing sources that may be having localized effects on the baseline that may not be captured by the single station. Several areas may be affected by heavy vehicle traffic, industrial operations and power generation facilities. For this reason, three additional monitoring locations will be sampled for select contaminants. The parameters identified that may impact these areas have been determined to consist primarily of PM10, NOx and SO_2.

Similarly, several sensitive receptors have been identified close to the proposed ISWMS. These include the Lakeside Villas residential development the Cayman International School and Glenwood Drive. Two additional sampling locations have been located at Lakeside Villas and the Cayman International School to measure baseline concentrations of select contaminants at these sensitive receptors.

4.1.1 PM10

One battery/solar powered continuous PM10 monitor will be installed at a site representative of the airshed downwind of the industrial and power generation area south of the site. Another will be placed at the Lakeside Villas. The small footprint of this analyzer will allow for placement where a full monitoring station would not be possible.

The PM10 instrument will be a Met-One E-Sampler or equivalent. These instruments operate on the principle of optical light scattering, a principle approved in the UK as noted in Section 2. These instruments have a linear response to particulate mass concentrations across their range.

4.1.2 NO_2 and SO_2 Passive Samplers

Diffusion based NO_2/SO_2 ambient air samplers will be used during the monitoring program. Three will be at sites that may be impacted by local combustion sources and another will be collocated with the continuous monitors at the primary monitoring station. Two more stations will be located at the sensitive receptor sites at Lakeside Villas and the Cayman International School.

Diffusion samplers are a type of passive sampler; that is, they absorb the pollutant to be monitored directly from the surrounding air and need no power supply. Passive samplers can be deployed over a wider area than

permanent monitoring stations, they are ideal for identifying locations where NO_2/SO_2 concentrations may be highest.

The NO_2 passive sample system uses a specially designed rain shelter to allow the passive sampler to be installed face downwards and to allow the air movement to cross the surface of the diffusion barrier. After exposure, the sampler media is extracted in the laboratory with de-ionized (DI) water. The extract is analyzed by Ion Chromatography. The sampling rate of the passive sampler is calculated using an equation which takes into account the dependence on associated meteorological factors.

The SO_2 passive sample system uses a specially designed rain shelter to allow the passive sampler to be installed face downwards and to allow the air movement to cross the surface of the diffusion barrier. After exposure, the sampler media is extracted in the laboratory with hydrogen peroxide. The extract is analyzed by using ion chromatography (IC). The sampling rate of the passive sampler is calculated using an equation, which takes into account the dependence on associated meteorological factors.

After an exposure period of approximately two weeks the passive samplers are collected and replaced with new ones. The absorbent material is returned to an accredited analytical laboratory for analyses of NO_2 and SO_2.by Ion Chromatography (IC).

Since the exposure period for the passive samplers is two weeks and the applicable standards for SO_2 are 15-minute, 1-hour and 24-hour means, conversion between averaging periods will be necessary. The Ontario Ministry of the Environment provides guidance on converting between averaging periods in their guidance document entitled “Procedure for Preparing an Emission Summary and Dispersion Modelling Report”, dated March 2018 (ESDM Procedure Document). Using this guidance, the two week samples can be converted to the averaging times of the air quality standards in Table 1 as follows:

$C0 = C1 \times F$

where, C0 = the concentration at the averaging period t0

C1 = the concentration at the averaging period t1

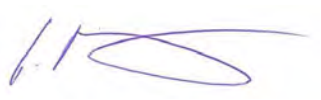
F = factor to convert from the averaging period t1 to the averaging period t0

$= (t1/t0)n$

and where, the exponent n is 0.28, which is generally representative of average conditions across a range of atmospheric stabilities.

4.1.3 Meteorological Equipment

Meteorological (met) equipment will be located at three (3) stations to continuously monitor wind speed, wind direction and ambient temperature at a minimum. The fully instrumented station will monitor wind speed, wind direction, ambient temperature and barometric pressure.



Therefore, the entire network that will be monitored to provide the baseline concentrations of air contaminants for the project will consist of seven (7) stations. These stations, including the pollutants to be monitored and the exact method/equipment to be used at each station is detailed in Table 2. The locations of each station are provided in Figure 3.

4.2 Duration of Baseline Monitoring

Seasonality on the Cayman Islands consists of a wet and a dry season. The dry season usually begins in early November and lasts until April. It is proposed for the EIA that four (4) months of baseline monitoring will be sufficient to cover all seasons in the Cayman Islands. The monitoring will take place beginning in October 2021 which will measure emissions occurring during the end of the rainy season. It is proposed that the baseline monitoring continue through November until early February covering 3 months during the dry season. The dry season will be the worst-case scenario for local emissions as rain will wash gaseous and particulate bound emissions from the air during the wet season.

Should you have any questions on the above, please do not hesitate to contact us.

1. Introduction

The following report details the ambient air monitoring program (Program) that was conducted in support of the Cayman Islands Integrated Solid Waste Management System (ISWMS) Environmental Impact Assessment (EIA).

An Air Quality Method Statement (Method Statement) was submitted by GHD and reviewed by the Cayman Islands Government and their consultants. The Method Statement received comments and was approved on October 8, 2021. It was agreed that an ambient air monitoring program (AAMP) be established to monitor the background (baseline) ambient air concentrations of air contaminants in the vicinity of the future location of the ISWMS that will be located proximate to the current site of the George Town Landfill (GTLF).. The AAMP was initiated and operated by GHD, Valley Environmental Services (VES), Dart Enterprises Cayman (Dart) and the Department of Environmental Health (DEH).

The list of air contaminants that were monitored and measured for the program consisted of air emissions that are currently being emitted from the existing sources in the vicinity of the GTLF as well as additional emissions that are expected to be emitted from the new sources that will be associated with the ISWMS facility.

The AAMP was initiated on October 24, 2021 and lasted for approximately four months, encompassing approximately one month of wet season followed by three months of dry season. The AAMP consisted of United States Environmental Protection Agency (USEPA) Federal Reference Method (FRM) and Federal Equivalent Method (FEM) non-continuous and continuous sampling as well as passive monitoring, hydrogen sulphide (H_2S) and odour assessments of existing conditions.

After the assembly of the monitoring stations and initial calibration of the monitoring equipment by GHD and VES, the AAMP was run by staff from Dart and DEH. Prior to the beginning of the Program, training was provided by GHD and VES on all aspects of the equipment being used in the AAMP. Virtual and on-site training was provided by air quality experts from GHD and VES from October 8 to October 31, 2021 on the non-continuous and continuous monitors respectively. Calibration, field, and laboratory procedures for all pieces of equipment and sampling techniques were video recorded by Dart for future reference.

2. Air Contaminants Measured and Monitored for the Program

Air contaminants that were measured and monitored included the compounds that are expected to be emitted from the ISWMS as well as compounds currently being emitted from existing sources in the vicinity of the GTLF.

2.1 Emissions Expected from the ISWMS

As noted in the Method Statement, the ISWMS will incorporate the following potential air emission sources:

– An Energy Recovery Facility (ERF) for the treatment of Municipal Solid Waste (MSW)
– A Green Waste Facility for outdoor processing (composting and mulching) of organic waste
– An End-of-Life Vehicle (ELV) and Scrap Metal Processing Facility
– A Construction and Demolition (C&D) Waste Facility
– A Bottom Ash Processing Facility
– A Medical Waste Processing Facility

– A Landfill Gas Facility and
– A Residual Waste Landfill

Based on guidance such as the **EU Industrial Emissions Directive (IED – 2010/75/EU)** which stipulates acceptable emission values to atmosphere for industry, including waste incineration processes such as the ERF, as well as the parameters that should be monitored from these processes. These parameters are as follows:

– Dioxins and Furans (PCDD/PCDF)
– Polycyclic Aromatic Hydrocarbons (PAHs)
– Dust (particulate matter < 10 microns [PM10])
– Gaseous and volatile organic compounds (VOC)
– Hydrogen Chloride (HCl)
– Hydrogen Fluoride (HF)
– Sulphur Dioxide (SO_2)
– Oxides of Nitrogen (NOx)
– Carbon Monoxide (CO)
– Heavy Metals:
  - Cadmium (Cd)
  - Thallium (Tl)
  - Mercury (Hg)
  - Antimony (Sb)
  - Arsenic (As)
  - Lead (Pb)
  - Chromium (Cr)
  - Cobalt (Co)
  - Copper (Cu)
  - Manganese (Mn)
  - Nickel (Ni)
  - Vanadium (V)

2.2 Existing Local Air Contaminants

Current emissions from local sources were considered for the monitoring program. These emission sources were inventoried and include the following sources and the primary compounds they are likely to be emitting:

– Esterley Tibbetts Highway (NOx, CO, particulate matter<2.5 microns (PM2.5))
– GTLF (PM10, hydrogen sulphide (H_2S), metals from car dismantling, odour, bioaerosols))
– Wastewater Treatment Plant (WWTP) (Total Reduced Sulphur (TRS), H_2S, odour)
– Current Medical Waste Incinerator at GTLF (emissions profile similar to the proposed ERF in Section 2.1, odour)
– Asphalt Plant (NOx, SO_2, CO, PM10, PAH, odour)
– Cement, Concrete and Concrete Batching Plants (NOx, SO_2, CO, PM10)
– Cayman Spirits Company (VOC)
– Cayman Utilities (CUC) Diesel Fueled Power Plant (NOx, SO_2, CO, PM2.5, odour)
– New Airport Connector Road Construction (PM10, metals)
– Existing shoreline and mangroves near the GTLF (odour, H_2S)

– Owen Roberts International Airport
– Cruise ships and port

The existing sources of air contaminants in the vicinity of the ISWMS are indicated in Figure 1.

2.3 Final List of Parameters, Sample Methodology, Sampling Duration and QA/QC

As noted in the Method Statement, the finalized and agreed-upon list of parameters and locations for monitoring the baseline conditions of the existing and expected emissions from the ISWMS are provided in Table 1 and Figure 2. Table 1 summarizes the parameters, monitoring methodology and monitoring frequencies for each monitoring station. Monitoring methods were continuous, non-continuous and/or passive. Figure 2 shows the seven air monitoring station locations and the parameters that were sampled at each station.

The final decisions for the sampling locations and sampling methodology were based on a hybrid approach of United Kingdom/European Union (UK/EU) ambient air monitoring methods, USEPA ambient air monitoring methods and Ontario (Canada) monitoring methods and sample analyses. This was decided because although the Cayman Islands are a British territory, the geographical proximity to North America meant that US/Canadian environmental labs were better suited for shipping and analysis of the samples and sourcing of specific ambient air monitoring equipment, such as continuous emission monitors (CEMs). The UK/EU, USEPA and Ontario approaches to sample collection and analysis, and continuous/passive monitoring of ambient air are generally very similar. For the purposes of this report, CEMs refers to FEM continuous analyzers that measure ambient air concentrations of specific parameters in the part per billion (ppb) range and not specifically source emissions from stacks at a facility that measure in the part per million (ppm) and percent range of concentrations.

2.3.1 Air Quality Standards and Averaging Periods

The standards that were used for the determination of compliance with ambient air criteria was taken from the **UK National Air Quality Objectives** (NAQO). These applicable air quality standards and associated time averaging periods are provided in Table 2.

There are no ambient air quality limits for H_2S in the NAQO. For reference, the Ontario (Canada) limits for H_2S have been used (a 10-minute 13 µg/m^3 for odour).

There are no limits for dioxins and furans in the NAQO. For reference, the Ontario limits have been used which is based on World Health Organization (WHO) guidance. The standard for dioxins and furans is 0.1 pgTEQ/m^3.

In cases where the sample durations differ from the averaging period of the standard, it was agreed in the Method Statement that a conversion factor based on the Ontario Ministry of the Environment guidance document entitled **Procedure for Preparing an Emission Summary and Dispersion Modelling Report**, dated March 2018 (ESDM Procedure Document) be used. Using this guidance, the sample results from a specific averaging period can be converted to the averaging times of the air quality standards. This guidance was applied to the following instances:

– For the VOCs monitored at Station 1, to convert from a 24-hour averaging period to 1-hour averaging period.
– For HF and HCl monitored at Station 1, to convert from a 24-hour averaging period to 1-hour averaging period.
– For SO_2 monitored using passive samplers at Stations 1 through 6, to convert from a 2-week averaging period to a 15-min averaging period.

In the case of the passive samples that were deployed for 2 weeks, a conversion to 1-hour and 24-hour averaging periods was based on a factor by comparing the 1-hour average CEMS data over two-week periods for NO_2 and SO_2. In the case of NO_2, to convert the Passive Samplers 2-week averaging period to a 1-hour averaging period, the ratio of CEMS's 90th percentile to CEMS's average for that corresponding period was multiplied with the Passive Samplers 2-week averaging period values. The ratio of CEMS's 90th percentile to CEMS's average for each sampling period is listed under Table B-15. A similar approach was followed for SO_2 o convert the Passive Samplers 2-week averaging

period to a 1-hour averaging period; and the ratios used for SO_2 are listed under Table B-16. For SO_2 to convert the Passive Samplers 2-week averaging period to a 24-hour averaging period, the ratio of CEMS's (24-hour rolling average) 90th percentile to CEMS's (24-hour rolling average) average for that corresponding period was multiplied with the Passive Samplers 2-week averaging period values. The ratio of CEMS's (24-hour rolling average) 90th percentile to CEMS's (24-hour rolling average) average for each sampling period is listed under Table B-16.

The annual average for the passive, continuous and non-continuous samples were the average of the applicable sample data set for the monitoring period.

2.3.2 Quality Assurance/Quality Control (QA/QC)

A comprehensive Quality Assurance/Quality Control (QA/QC) program was completed for the AAMP that included, but was not limited to the following requirements:

- Equipment calibrations according to the Methods
- USEPA Protocol 1 calibration gases
- Data editing and data reduction according to standardized procedures and methods
- Data recorded on standardized field forms including all information required
- Transportation of samples by chain of custody procedures
- Standardized sample identification system
- Provision of sample media and analyses performed by of accredited environmental air quality laboratories
- Observe sample storage requirements and holding times for each parameter
- Clean, dedicated sample recovery area with sample refrigeration (4 degrees C)
- Climate control for dedicated air quality analyzers

The QA/QC procedures for each parameter are detailed in Appendix B.

2.4 Greenhouse Gas Emissions (GHG)

Certain sources noted in Sections 2.1 and 2.2 above may also produce greenhouse gases such as carbon dioxide (CO2) and/or methane (CH4). The baseline concentrations for these parameters were not measured during the AAMP but were estimated using information from the the Cayman Islands Department of Environment (DOE). According to the DOE's Carbon Footprint Statement (**https://doe.ky/sustainable-development/carbon-footprint/**), the UK is a signatory to both the Kyoto Protocol and the United Nations Framework Convention on Climate Change (UNFCCC). Through the UK, the UNFCCC and Kyoto Protocol were extended to the Cayman Islands in March 2007. As a result, statistics for the Cayman Islands were incorporated into the UK's overall emissions figure presented to the UNFCCC. Aether Consulting in the UK used raw data to calculate the equivalent greenhouse gas emissions produced based on assumed emissions factors for the electricity generated by CUC and fuel used in road transport. The Department of Environment (Cayman Island Government) gathers data on electricity generation and fuel consumption. Additionally, information is gathered and provided on the use of solvents, waste management, mobile equipment, aviation and air travel, shipping, agriculture, and forestry. According to the DOE, carbon dioxide (CO_2) the major greenhouse gas produced by the Cayman Islands, with methane and other greenhouse gases being negligible in contrast. The Cayman Islands released 726,000 tonnes of CO_2 equivalent in 2007 and about 714,000 tonnes of CO_2 equivalent in 2014. Power generation accounts for most of the greenhouse gas emissions, accounting for 65% of all CO_2 emissions since 2007. As per the Cayman Islands 2020 Compendium of Statistics **https://www.eso.ky/UserFiles/right_page_docums/files/uploads/the_cayman_islands_compendium_of_statist-14.pdf**), it reports that 718,000 tonnes of CO_2 equivalent was released in 2011. Based on the data from 2007, 2011 and 2014, and an assumption of marginal growth in greenhouse gas emissions since 2014, it is estimated that the current annual greenhouse gas emissions from the Cayman Islands is approximately 720,000 tonnes of CO_2 equivalent.

2.5 Odour

Odour was identified as an air emission by-product from certain sources noted in Sections 2.1 and 2.2 above. As per Section 2.1 of the Method Statement, an odour assessment survey was conducted by GHD during the daytime and early evening hours of October 28, 2021. This is further discussed in Section 4.14.

Odour assessment surveys are guided by EN 264086 Parts 1 and 2. A combination of odour assessment tools were used for determining the existing conditions as follows:

1. Sensory Assessment using field olfactometry (Nasal Ranger™) to measure the concentrations of existing odours from upwind sources (mangroves, stagnant pond and WWTP) and existing onsite sources. The Nasal Ranger is a portable field olfactometer that is used to quantify odour intensity in ambient air. Prior to the field work the user of the olfactometer is 'calibrated' to ensure their sense of smell is neither hyperosmic (overly sensitive) nor anosmic (under sensitive). With the calibrated user, the Nasal Ranger determines ambient odour Dilution-to-Threshold (D/T) concentration objectively by diluting the odour with carbon filtered air at various ratios (2, 4, 7, 15, 30 and 60. The dilution ratio tjerhat corresponds when the odour is no longer detected is the D/T of the odour in ambient air. Photos of the Nasal Ranger being used in the field are provided in Appendix D.
2. Compound analysis of existing upwind and downwind H_2S readings using a Jerome 631X portable H_2S analyzer that uses gold-film sensor technology to measure low-level (0.003 to 50 ppm).

During the assessment, special consideration was given to Section 3 of the UK **Guidance on the Assessment of Odour for Planning** (Institute of Air Quality Management, July 2018) (UK Planning) as noted in Section 2.4.1 of the Method Statement and discussed further in Section 4.14.

The 'complaints' criterion for the assessment of sewage odours from UK Planning is the 98th percentile 1-hour concentration of 5 OU/m^3 at the receptor.

2.6 Bioaerosols

Bioaerosols were considered as part of the determination of existing conditions for the project. In consideration of the potential effect of bioaerosols at sensitive receptors the following UK guidance documents were referenced:

1. *Technical Guidance Note (Monitoring) M9 Environmental Monitoring of Bioaerosols at Regulated Facilities, Environmental Agency, July 2018*
2. *Occupational and Environmental Exposure to Bioaerosols from Composts and Potential Health Effects - A Critical Review of Published Data, 2003*
3. *Guidance on the Evaluation of Bioaerosol Risk Assessments for Composting Facilities; Leeds University, 2008*
4. *Site Specific Bioaerosol Risk Assessment, WRM, 2020*

Bioaerosols are found naturally within the environment. They consist of airborne particles that contain living organisms, such as bacteria, fungi and viruses or parts of living organisms, such as plant pollen, spores and endotoxins from bacterial cells or mycotoxins from fungi. The components of a bioaerosol range in size from around 0.02 to 100 micrometres (µm) in diameter. The size, density and shape of a bioaerosol will affect its behaviour, survivability and ultimately its dispersion in the atmosphere.

Composting and anerobic digestion appear to be the largest sources of bioaerosols. The dependence on microorganisms to degrade the organic material, and the way in which the material is processed make biological treatment facilities a source of bioaerosols.

Bioaerosols degrade and disperse in the air a short distance away from the source. This distance appears to be within 200 m to 250 m depending on the meteorological conditions. Because of the nature of bioaerosols, their impact is largely on the workers who are exposed to them daily at close proximity and therefore can be a worker exposure issue.

The UK Environment Agency's policy position on composting and potential health effects from bioaerosols (2007) is that they will:

> "take into account the potential effects of bioaerosols on human health when authorizing new waste composting facilities or changes to existing facilities. To do this, applicants will have to provide us with a site-specific bioaerosol risk assessment if there is a workplace or dwelling within 250 metres of the composting site boundary. The assessment must be based on clear scientific evidence and show that bioaerosols can and will be maintained at appropriate levels at any workplace or boundary of a dwelling"

Neither composting nor anerobic digestion are currently occurring at the GTLF. Composting of green waste will be a component of the proposed ISWMS which will be well within a 250 m buffer separating the nearest offsite sensitive receptors. The ISWMS facility will conform to an Environmental Management Plan to adopt operations and mitigation measures to control activities that may generate and affect the release of bioaerosols.

Therefore, an assessment of the existing conditions of bioaerosols was not undertaken. The ISWMS will be designed such that the potential health affects to workers are minimized.

3. Description of Baseline Monitoring Station Locations

This section summarizes the basis for the selection of the main monitoring station (Station 1) and the six (6) supporting monitoring stations used in the Program as well as their specific roles in determining the overall baseline values for the EIA.

3.1 Existing Meteorological Data

A review of the existing meteorological data that was available to GHD from Owen Roberts International Airport (2011 to 2020) at the onset of the Program, which was presented in the Method Statement, showed that the prevailing wind directions are well defined and are almost exclusively blowing in an east to west direction with slight deviations.

3.2 UK Guidance

As per the UK Department of Environment, Food and Rural Affairs (DEFRA) at **https://uk-air.defra.gov.uk/networks/site-types**, a background monitoring station should be located as follows:

> *Located such that its pollution level is not influenced significantly by any single source or street, but rather by the integrated contribution from all sources upwind of the station e.g., by all traffic, combustion sources etc. upwind of the station in a city, or by all upwind source areas (cities, industrial areas) in a rural area. These sampling points shall, generally, be representative for several square kilometres.*

Based on this guidance the main, fully equipped baseline monitoring station was located, to the extent possible, downwind of the proposed ISWMS facility based on prevailing wind conditions, but also downwind of other existing significant sources of emissions including all the emissions sources noted in Section 2.2. This station location is identified as Station 1 on Table 1 and Figure 2.

Six other monitoring stations were located throughout Georgetown to specifically measure concentrations of dust (PM10) and/or H_2S and/or NOx and SO_2 compounds at sensitive receptors such as schools, residential areas and the downtown core located closer to existing sources such as highways, the WWTP, and the industrial areas of Georgetown including the CUC, and asphalt plant sources. The six other stations, are identified as Stations 2 through 7 on Table 1 and Figure 2.

3.3 General Description and Purpose of Each Monitoring Station

3.3.1 Station 1 Cox Lumber

Station 1 was the primary monitoring station, consisting of an air-conditioned container that housed the following FRM/FEM and associated equipment:

1. Teledyne API (TAPI) T200 NOx Chemiluminescence analyzer
2. TAPI T300 CO Gas Filter Correlation analyzer
3. TAPI T100 SO_2 UV Fluorescence analyzer
4. MetOne Bata Attenuation Monitor (BAM) 1020 Continuous PM2.5 Monitor
5. Zero Air Generator
6. EPA Protocol 1 Calibration Gases (NO, SO_2 and CO)
7. HF and HCl impinger samplers
8. A 20ft meteorological tower (above the roof of the container) with an RM Young wind speed (WS) and wind direction (WD) monitor including relative humidity (RH), and ambient temperature (AT)
9. A dedicated sample recovery area including a refrigerator for interim storage of samples requiring cool storage

A rooftop area with a railing also housed non-continuous samplers such as:

1. FRM high volume PM10 sampler for the collection of PM10 and metals in the PM10 fraction for 24 hours every six days according to the National Air Pollution Surveillance (NAPS) schedule
2. FRM medium volume (PUF) sampler for the collection of semi-volatiles including PCDD/PCDF and PAH compounds for 24 hours every six days according to the NAPS schedule
3. Summa canister for the collection of VOCs for 24 hours every six days according to the NAPS schedule
4. Passive monitors for NO_2 and SO_2 for correlation purposes

This station was located according to the criteria for the location of a background monitoring station away from major roads and trees and was not influenced significantly by any specific emissions source. The station was located downwind of the future site of the ISWMS and the ERF and other significant emissions sources in the area.

Pictures of Station 1 are provided in Appendix D.

3.3.2 Station 2 Paddington Place

Station 2 was used for passive monitoring of NO_2 and SO_2 from industrial areas, the CUC, and road traffic emissions. Paddington Place was located close to the Esterly Tibbetts highway and a major roundabout.

3.3.3 Station 3 George Town Primary School

Station 3 was used for passive monitoring of NO_2 and SO_2 for sensitive receptors at the George Town Primary school.

3.3.4 Station 4 OPY 20

Station 4 was used for passive monitoring of NO_2 and SO_2 and continuous monitoring of PM10 and WS/WD from the downtown core.

3.3.5 Station 5 Lakeside

Station 5 was used for passive monitoring of NO_2 and SO_2, continuous monitoring of PM10 and H_2S, and WS/WD near sensitive receptors at this residential complex located directly downwind of the GTLF. The Lakeside monitors are also located very close to the edge of Esterly Tibbetts highway and will therefore show impacts from road traffic. Pictures of Station 5 are provided in Appendix D.

3.3.6 Station 6 Cayman International School (CIS)

Station 6 was used for passive monitoring of NO_2 and SO_2 for the sensitive receptors at CIS.

3.3.7 Station 7 Laundry

Station 7 was used for continuous monitoring of H_2S from the WWTP and other H_2S sources upwind of the GTLF, as well as continuous monitoring of WS/WD.

3.4 Summary of Issues and/or Changes to the AAMP

The following is a list of technical issues and/or changes to methods and approaches that were proposed in the Method Statement to those that occurred during the AAMP.

3.4.1 HCl/HF Method Change

The approach was changed from the USEPA OTM-40 as proposed in the Method Statement to a modified USEPA Method 26. The change occurred due to lack of equipment and laboratory availability for OTM-40. The change caused no issues for data quality and/or availability.

3.4.2 Passive Sampling

The passive sampling program started approximately 3 weeks after the AAMP due to logistics and supply chain issues. The passive program was shorted from 10 proposed samples total to 9 samples total.

3.4.3 Wind Speed and Wind Direction

Three proposed sites for WS, WD and ambient temperature (AT) at Stations 4, 5 and 7 were unavailable due to equipment issues. GHD instead acquired WS and WD data from Owen Roberts Airport to supplement the meteorological data from Station 1.

3.4.4 H_2S

The continuous H_2S data collected upwind and downwind of the GTLF during the AAMP had considerable data gaps due to power issues and saturation/regeneration of the gold-film sensors. H_2S data collected at Station 5 was likely influenced by a large holding tank containing sewage located close to the instrument although it is not known the extent this influence may have had on the values collected at this location.

4. Results and Discussion

The background concentrations for the air contaminants measured at each Station are summarized in Table 3. For the various air contaminants and their averaging periods (except for the annual averaging period), the 90th percentile

value was used to represent the background concentration. For the air contaminants for which the annual averaging period is applicable, the average of the sampling data set at the applicable Station was used.

4.1 NO_2

The NO_2 concentrations were measured at Station 1 with CEMS. Passive samples for NO_2 were monitored at six Stations (1 through 6), including a co-located passive sampler at Station 1. The 1-hour and annual background concentrations are provided in Table 3. The continuous data for NO_2 is provided in Tables A-1 and A-2 in Appendix A.

Combustion gas emissions were relatively stable with low concentrations measured throughout the monitoring period. Station 1 was impacted by combustion gas emissions from CUC when the winds were blowing from the facility toward the NO_2 monitors at Station 1 at approximately the 101-to-110-degree wind direction.

4.2 CO

The TAPI CEM located at Station 1 was used for the baseline concentrations for CO. The 8-hour background concentration for CO is provided in Table 3. The continuous data for CO is provided in Tables A-1 and A-2 and A-4 in Appendix A.

Combustion gas emissions were relatively stable with low concentrations measured throughout the monitoring period. Station 1 was impacted by combustion gas emissions from CUC when the winds were blowing from the facility toward the CO monitors at Station 1 at approximately the 101-to-110-degree wind direction.

4.3 SO_2

Continuous samples for SO_2 were monitored at Station 1 and passive samples were collected at six Stations (1 through 6), including a co-located passive sampler at Station 1. The 1-hour, 24-hour and 15-minute background concentrations are provided in Table 3. The continuous data for SO_2 is provided in Tables A-1, A-2, A-3 and A-4 in Appendix A.

Combustion gas emissions were relatively stable with low concentrations measured throughout the monitoring period. Station 1 was impacted by combustion gas emissions from CUC when the winds were blowing from the facility toward the SO_2 monitors at Station 1 at approximately the 101-to-110-degree wind direction.

4.4 PM2.5

The BAM 1020 CEM with the PM2.5 cut cyclone located at Station 1 was used for the baseline concentrations for PM2.5. The PM2.5 annual background concentration is provided in Table 3. The annual PM 2.5 background concentration was approximately 5.1 µg/m3, which is 26% of the limit annual limit of 20 µg/m3. The edited continuous data for PM2.5 is provided in Tables A-1 and A-2 in Appendix A.

4.5 WS/WD, RH and Temperature

The wind speed and wind direction results collected during the AAMP at Station 1 are provided graphically in Figure 3. The windrose in Figure 3 shows that the predominant wind directions are blowing from the easterly direction with lower percentages from the south, southeast, northeast, and northerly directions and negligible winds blowing from the southwest, west and northwest. Wind speed and wind direction data was also obtained from the Owen Roberts Airport in George Town during the monitoring period. Note that WS/WD data is not collected at Owen Roberts Airport for 6 hours per day from approximately 4am to 10 am. The Owen Roberts Airport windrose is provided in Figure 4. The wind directions shown in Figures 3 and 4 are comparable. The percentage of higher wind speeds in Figure 4 compared to Figure 3 is due to the 6 hours of data missing between 4 am and 10 am at the airport, data that would be generally lower wind speeds than the rest of the day. The data for WS/WD from Station 1 is provided in Table A-1 in Appendix A.

4.6 H_2S

H_2S was monitored continuously upwind and downwind of the GTLF at Station 7 and Station 5 respectively. These stations were located to monitor specific sources of H_2S, namely the WWTP and the GTLF, so they may not be representative of true background concentrations of areas outside of the influence of these two specific sources. In addition, the H_2S values reported in Table 3, Table A-7, Table A-8 and Table A-9 are based on data collected during the monitoring period with some considerable data gaps as noted in Section 3.4.4 and the tables noted above in Appendix A. H_2S data collected at Station 5 was likely influenced by a large holding tank containing sewage located close to the instrument although it is not known the extent this influence may have had on the values collected at this location.

GHD could not locate a corresponding EU or UK ambient air quality limit for H_2S. For reference, a 10-minute limit was used from the Ontario guidance 0f 13 $\mu g/m^3$. The comparison of this limit to H_2S concentrations measured at Lakeside Station 5 produced the only air quality limit exceedance during the program. This exceedance was likely influenced by the location of the monitor as noted above. It should also be noted that H_2S is not considered as a by-product of the emissions from the ERF, so ambient concentrations should be lower after construction of the ISWMS.

4.7 PM10

PM10 was measured non-continuously from Station 1 every 6 days for a 24-hour period for the monitoring duration, for a total of 20 samples.

PM10 was also measured continuously from Stations 4 and 5. The continuous PM10 concentrations from these two stations show the impacts of vehicle traffic in the downtown areas and the Esterly Tibbetts highway.

The 24-hour and annual PM10 background concentrations from the continuous and non-continuous samplers are provided in Table 3. The continuous data statistical summaries for PM10 are provided in Table A-5 and A-6 in Appendix A. The laboratory results for the non-continuous PM10 samples are provided in Appendix B and summarized in Table B-1 and Table B-2. The field sampling forms for non-continuous sample collection are provided in Appendix C.

4.8 Metals

Metals were measured non-continuously from the PM10 fraction at Station 1 every 6 days for a 24-hour period for the monitoring duration for a total of 20 samples. As noted in Table 2, cadmium, arsenic, lead and nickel are the only metals with applicable limits in the UK Air Quality Objectives. The annual background concentrations for cadmium, arsenic, lead, and nickel are provided in Table 3. The laboratory results for the non-continuous metals samples are provided in Appendix B and are summarized in Table B-3 and Table B-4. The field sampling forms for non-continuous sample collection are provided in Appendix C.

The annual background concentrations measured for cadmium, arsenic, lead and nickel are all well below 1% of their applicable annual limits in the guidance.

4.9 PCDD/PCDF

Dioxins and furans were measured non-continuously at Station 1 every 6 days for a 24-hour period for the monitoring duration for a total of 20 samples. The 24-hour dioxin and furan background concentrations are provided in Table 3. The laboratory results for the non-continuous dioxin and furan samples are provided in Appendix B and summarized in Table B-5 and Table B-6. The field sampling forms for non-continuous sample collection are provided in Appendix C.

A representative annual and 24 hour ambient air quality limit for dioxins and furans is not available from the **UK** NAQO**.** For the purposes of this study, a dioxin and furan limit of 0.1 $pgTEQ/m^3$ was used from the Ontario (Canada) Ambient Air Quality Criteria (AAQC). The dioxins and furans background values was calculated by using the 90th percentile of the midpoint between upper bound and lower bound TEQ/m^3 lab results.

The 24 hour background concentration of dioxins and furans is 0.013 pgTEQ/m^3 which is 13% of the standard of 0.1 pgTEQ/m^3.

4.10 PAHs

PAHs were measured non-continuously at Station 1 every 6 days for a 24-hour period for the monitoring duration, for a total of 20 samples. The surrogate PAH standard in the NAQO is based on the benzo(a)pyrene (BaP) concentration as noted in Table 2. The annual BaP background concentration is provided in Table 3. The laboratory results for the non-continuous PAH samples are provided in Appendix B and summarized in Table B-7 and Table B-8. The field sampling forms for non-continuous sample collection are provided in Appendix C.

The background concentration of BaP is approximately 0.08 ng/m^3 which is 31% of the annual standard of 0.25 ng/m^3 from the NAQO.

4.11 VOC

VOCs were measured non-continuously at Station 1 every 6 days for a 24-hour period for the monitoring duration, for a total of 20 samples. The NAQO air quality standard for VOCs is based on the benzene concentration as noted in Table 2. The hourly and annual benzene background concentrations are provided in Table 3. The laboratory results for the non-continuous VOC samples are provided in Appendix B, and summarized in Table B-9, Table B-10, and Table B-11. The field sampling forms for non-continuous sample collection are provided in Appendix C

The annual and 1-hour background concentrations of benzene are approximately 0.5 and 1.6 µg/m^3 respectively which are 3% and 1% of the respective NAQO standards.

4.12 HF/HCl

HCl/HF were measured non-continuously at Station 1 every 6 days for a 24-hour period for the monitoring duration, for a total of 20 samples. The hourly background HCl concentration and the hourly and annual background HF concentrations are provided in Table 3. The laboratory results for the non-continuous HF/HCl samples are provided in Appendix B, and summarized in Table B-12, Table B-13, and Table B-14. The field sampling forms for non-continuous sample collection are provided in Appendix C.

The HCl and HF background concentrations are well below their respective NAQO standards.

4.13 Passive Monitoring for NO_2 and SO_2

Passive samples for NO_2 and SO_2 were deployed at Stations 1, 2, 3, 4, 5 and 6 for nine (9) two-week periods. The hourly and annual NO_2 concentrations from each Station are provided in Table 3. The two-week concentrations were converted to hourly and annual concentrations as per the method outlined in Section 2.3.1.

The 15 minute, 1-hour, and 24-hour SO_2 concentrations from each Station are provided in Table 3. The two-week concentrations were converted to 15 minute, 1-hour and 24-hour concentrations as per the method outlined in Section 2.3.1. The laboratory results for the passive samples are provided in Appendix B and summarized in Table B-15 and Table B-16.

The background concentrations of the passively monitored NO_2 and SO_2 are in the same range as the concentrations measured continuously at Station 1 with minor locational variations based on proximity to sources of these products of combustion.

4.14 Odour Assessment Survey

As discussed in Section 2.5, an odour assessment survey was undertaken on October 28, 2021, by representatives from GHD, Dart and DEH during the mid-afternoon and again in the evening hours as it was communicated to GHD by

local representatives, that in some cases, odour can increase at night. The odour assessment took place downwind of the identified odour sources and at sensitive receptors close to the GTLF. The odour assessment locations are shown on Figure 5.

A complaints history was not retrieved or compiled for the assessment survey.

During the day and evening of October 28, the wind was blowing mildly from the south to the north at an average of 2.4 m/s and 178 degrees respectively. The meteorological data from Station 1 during the odour sampling is provided in Table A-1 in Appendix A from 10:59 to 20:59 on October 28, 2021.

During the odour monitoring period, the following point and area sources were assessed qualitatively and/or quantitatively for odour and H_2S concentrations if applicable:

– CUC
– WWTP
– GTLF
– Mangroves and shoreline areas
– Medical Waste Incinerator (MWI)
– Asphalt Plant

In addition, the following sensitive receptor locations were assessed qualitatively for odour and/or quantitatively for odour and H_2S concentrations if applicable:

– Cayman International School
– Lakeside Condominiums

4.14.1 CUC

A slight odour of diesel exhaust was detected by GHD directly downwind of the CUC at the location shown on Figure 5. A measurement using the Nasal Ranger showed this odour was not detected at a 4:1 dilution.

4.14.2 WWTP

During normal WWTP operations, sewage is stored in settling ponds that are open to atmosphere. These ponds normally produce baseline sewage odour and can regularly emit H_2S emissions resulting in part per billion (ppb) range downwind concentrations. H_2S data has been collected by H_2S monitors operated by Dart located upwind and downwind of the WWTP since 2016.

During the odour assessment survey, the baseline odour condition was measured directly downwind of the WWTP settling ponds at the locations shown in Figure 5. GHD used a Nasal Ranger to quantify the odour concentrations at these locations in conjunction with portable Jerome gold-film analyzer H_2S measurements, taken at the same time and location. At the location which was approximately 50 m downwind of the WWTP settling ponds, the odour was detected from the Nasal Ranger at a dilution of 15:1 but was not detected at 30:1. The H_2S concentration associated with this odour was measured simultaneously and was recorded at between 177 to 233 ppb.

As noted in Section 2.5 the ‘complaints’ criterion for the assessment of sewage odours from UK Planning is the 98^{th} percentile 1-hour concentration of 5 OU/m^3 at a receptor. For context, an instantaneous measurement of between 15 and 30 OU at the WWTP property boundary noted above could have the potential to cause odour complaints at the nearest receptor (CIS) depending on the meteorological conditions and the duration of the event.

At intermittent periods, raw sewage water is pumped into the settling ponds if the WWTP capacity is exceeded. This activity produces intermittent spikes in odour and H_2S concentrations as witnessed by local representatives of Dart and DEH. This activity was not witnessed or recorded by GHD during the odour assessment survey.

4.14.3 GTLF

The active face of the GTLF was assessed for odour as was the covered landfill mound. While standing downwind of the mound, a distinctive odour of landfill gas was detected with no dilution, but not by the Nasal Ranger at a 4:1 dilution. H2S concentrations from downwind of the mound were </=5ppb.

The distinctive odour from the active landfill face was detected downwind at the entrance to the CIS as shown on Figure 5 with no dilution, at approximately 460 m from the active tipping area. The odour was not detected by the Nasal Ranger at a 4:1 dilution. H_2S was not detected at this location.

4.14.4 Upwind Mangroves and Shoreline Areas

As part of the odour assessment survey, mangroves and shoreline locations were assessed for odour and H_2S concentrations. Close to the shoreline and directly east of the GTLF and the WWTP as shown on Figure 5 is a stagnant pond. The pond is a former mosquito trench that was cut off by the expansion of the GTLF and now contains stagnant water.

Odour assessment measurements did not show this pond as being a significant source of odour in either daytime or evening measurements. Nasal Ranger measurements did not detect the odour at a 4:1 dilution and H_2S measurements were </=5ppb. For comparison, on the shoreline the odour was similarly not detected by the Nasal Ranger at 4:1 and the H_2S measurements were </=5ppb. The detection limit of the Jerome gold film analyzer is 1 ppb.

As part of the construction of the new Airport Connector Road currently being completed, the stagnant pond will be drained and remediated by the placement of culverts to connect it to existing sources of drainage. As such the area should be re-assessed at that time.

4.14.5 Medical Waste Incinerator

The medical waste incinerator (MWI) is currently located adjacent to the WWTP and the GTLF. The MWI burns small individual bins of medical waste three days per week with daily cool-down periods in between. Due to COVID and the increased amounts of personal protective equipment (PPE) waste in 2021 and 2022, the MWI was burning more waste than it was before COVID. Pollution control consists of an afterburner on the incinerator stack. Odour from the MWI was assessed during the survey by standing downwind of the visible plume. The odour can be characterized as similar to burned plastic. The Odour Ranger did not detect the odour at a dilution above 15:1 at a location approximately 50 m from the MWI from the visible plume. The current MWI will be replaced by a new MWI in the proposed ISWMS development with best available control technology (BACT).

4.14.6 Asphalt Plant

The asphalt plant was not producing asphalt during the odour assessment survey. The odour from the asphalt-making process was therefore not evaluated. However, asphalt plants are known to produce a distinct asphalt odour.

4.14.7 Lakeside Condominiums

During the odour assessment survey, the Lakeside Condominiums were not directly located downwind of the GTLF, however it was noted that a sewage odour was present in the condominium parking lot adjacent to the Esterly Tibbetts Highway. The odour was identified to be coming from an onsite sewage holding tank located there. During the odour assessment survey, H_2S was not detected downwind of the holding tank. However, H_2S data collected from Station 5 (Lakeside) showed elevated H_2S readings approximately an order of magnitude above the background values collected at Station 7. It is therefore reasonable that the H2S monitor at Station 5 is being impacted by the Lakeside sewage holding tank located approximately 15m from the monitor.

4.14.8 Central Laundry Facility

At the time of the odour assessment a new facility called the Central Laundry was being built adjacent to the WWTP. The Facility will be the central laundry service for many hotels in the area and will have many emissions sources associated with the processing of commercial laundry. The main sources of emissions will be products of the combustion of LPG and water vapour. The presence or absence of odour from this facility should be included in any future odour assessment survey.

4.14.9 Conclusions of the Odour Assessment Survey

Many current odour sources in the vicinity of the GTLF will change with the construction of the ISWMS Facilities and the New Airport Connector Road. These changes are summarized as follows:

GTLF

The active face of the landfill will remain until the ERF facility has been commissioned at which time it is reasonable that odours will be significantly reduced as organics will be moved to outdoor composting windrows and combustible waste will be brought to the ERF. Landfill gas will be captured and flared until gas quality for other uses is examined. This will reduce the landfill gas odour from the mound and capped areas.

Upwind Mangroves and Shoreline Areas

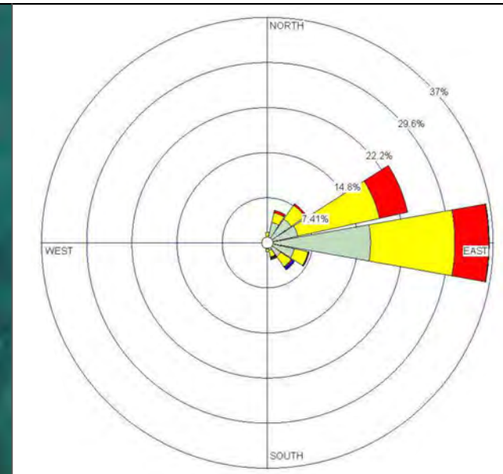
As part of the construction of the new Airport Connector Road currently being completed, the stagnant pond will be drained and remediated by the placement of culverts to connect it to existing sources of drainage.

Medical Waste Incinerator

The MWI will be moved and operate with BACT systems for pollution control that will reduce odour.

Central Laundry Facility

The Central Laundry facility may be a new source of odour through combustion of LPG and emissions of water vapour. However, the facility is not expected to be a noticeable odour source, particularly at the closest sensitive receptors located more than 500 m from the facility.



5. Conclusions

The AAMP was undertaken in general accordance with the Method Statement. If and where changes occurred, they were documented in Section 3.4.

The specified measurement principles and QA/QC program ensured that reliable data was collected for each measured parameter for the duration of the monitoring program.

All recorded baseline concentrations are shown in Table 3 and are below the applicable UK, EU, WHO or Ontario AAQC limits with the exception of H_2S at Station 5 (Lakeside). As noted in Sections 4.6 and 4.14.7 above, Station 5 was likely impacted by a local H_2S source located adjacent to the monitor.

In all cases, with the exception of annual averaging periods, 90^{th} percentile values were used to represent the background concentrations and are therefore conservative.

Table 3

Monitored Background Air Concentrations and Averaging Periods

Parameters	Station #	Station Name	CAS#	Averaging Period	Units	Background Concentration	Standard	% of the Standard
Sulphur Dioxide 15 Min Background Concentrations								
Sulphur Dioxide (SO_2) - CEMS	1	COX Lumber	7446-09-5	15-Minute	$\mu g/m^3$	4.551	266	2%
Sulphur Dioxide (SO_2) - Passive	1	COX Lumber	7446-09-5	15-Minute	$\mu g/m^3$	119.325	266	45%
Sulphur Dioxide (SO_2) - Passive	2	Paddington Place	7446-09-5	15-Minute	$\mu g/m^3$	47.258	266	18%
Sulphur Dioxide (SO_2) - Passive	3	George Town Primary School	7446-09-5	15-Minute	$\mu g/m^3$	30.717	266	12%
Sulphur Dioxide (SO_2) - Passive	4	OPY 20	7446-09-5	15-Minute	$\mu g/m^3$	22.447	266	8%
Sulphur Dioxide (SO_2) - Passive	5	Lakeside	7446-09-5	15-Minute	$\mu g/m^3$	251.646	266	95%
Sulphur Dioxide (SO_2) - Passive	6	Cayman International School	7446-09-5	15-Minute	$\mu g/m^3$	64.979	266	24%
Hydrogen Chloride 1 Hour Background Concentrations								
Hydrogen Chloride (HCl)	1	COX Lumber	7647-01-0	1 Hour	$\mu g/m^3$	32.279	750	4%
Hydrogen Flouride Annual Background Concentrations								
Hydrogen Flouride (HF)	1	COX Lumber	7664-39-3	Annual	$\mu g/m^3$	6.971	16	44%
Hydrogen Flouride 1 Hour Background Concentrations								
Hydrogen Flouride (HF)	1	COX Lumber	7664-39-3	1 Hour	$\mu g/m^3$	22.888	160	14%
Metals Annual Background Concentrations								
Cadmium (Cd)	1	COX Lumber	NA-03	Annual	$\mu g/m^3$	0.0002	5	0.003%
Arsenic (As)	1	COX Lumber	NA-02	Annual	$\mu g/m^3$	0.0018	6	0.031%
Lead (Pb)	1	COX Lumber	NA-08	Annual	$\mu g/m^3$	0.0020	0.25	0.816%
Nickel (Ni)	1	COX Lumber	NA-11	Annual	$\mu g/m^3$	0.0022	20	0.011%
Polycyclic Aromatic Hydrocarbons (PAHs) Annual Background Concentrations								
PAHs (Benzo(a)Pyrene)	1	COX Lumber	50-32-8	Annual	ng/m^3	0.0765	0.25	31%
Volatile Organic Compounds Annual Background Concentrations								
VOCs (Benzene)	1	COX Lumber	71-43-2	Annual	$\mu g/m^3$	0.503	16	3%
Volatile Organic Compounds 1 Hour Background Concentrations								
VOCs (Benzene)	1	COX Lumber	71-43-2	1 Hour	$\mu g/m^3$	1.587	195	1%
Hydrogen Sulphide 10 Min Background Concentrations								
Hydrogen Sulphide	5	Lakeside	7783-06-4	10 Min	$\mu g/m^3$	34.847	13	268%
Hydrogen Sulphide	7	Laundry	7783-06-4	10 Min	$\mu g/m^3$	2.788	13	21%
Dioxin and Furans 24 Hour Background Concentrations								
Mid Point PCDD/F TEQ (WHO 2005)	1	COX Lumber	-	24	$pgTEQ/m^3$	0.013	0.1	13%

Notes:

(1) For the various parameters and their averaging periods (except for the annual averaging period), the 90 th percentile value was used to represent the background concentration.
(2) For the various parameters for which the annual averaging period is applicable, the average of the entire sampling duration was used.
(3) PCDD/F - Polychlorinated Dibenzo-p-dioxins (PCDDs, Dioxins) and Polychlorinated Dibenzofurans (PCDFs, Furans),
(4) TEQ - Toxic equivalency of a dioxin or furan homologue to that of 2,3,7,8 PCDD.

Appendix C

Field Files and Calibration Files

Appendix C QA/QC Plan Cayman AAMP

1. Quality Assurance/Quality Control

1.1 CEMS

The CEMs were purchased specifically for this project. They were installed brand new out of the crate into the container racking. The following sections discuss the QA/QC program that was utilized for the CEMs.

1.1.1 NOx

The NOx CEM was calibrated prior to the start of the Program with EPA Protocol 1 calibration gases. The CEMs were spanned and zeroed nightly with the zero air generator and internal permeation tubes. After installation calibration was performed monthly using the calibration gases.

1.1.2 CO

The CO CEM was calibrated prior to the start of the Program with EPA Protocol 1 calibration gases. After installation calibration was performed monthly using the calibration gases.

1.1.3 SO_2

The SO_2 CEM was calibrated prior to the start of the Program with EPA Protocol 1 calibration gases. The CEMs were spanned and zeroed nightly with the zero air generator and internal permeation tubes. After installation calibration was performed monthly using the calibration gases.

1.1.4 BAM 1020 PM2.5

The BAM 1020 was leak tested and calibrated by VES upon installation. A PM2.5 cut cyclone was placed on the top of the sample inlet. Flow checks were completed every month as per the operator manual using a MetOne calibration orifice. The BAM 1020 calibrates itself before each reading by analyzing a blank portion of the tape prior to collecting and analyzing the sample using the principle of beta attenuation.

1.1.5 H_2S

The Jerome gold-film analyzers were calibrated on an annual basis at the AMETEK facility in the US.

The functionality of the analyzers were checked regularly using a Functional Test Module (FTM) at the DEH lab.

1.1.6 WS/WD

The RM Young Wind Speed and Wind direction monitor was calibrated prior to the AAMP by VES. At the beginning of the program the wind direction was confirmed using a compass and verified by calculating the magnetic declination and adjusting the direction to true north by using online maps and identifying an object that is visibly in the true north direction. In addition, the data was verified by comparing the measurements at Station 1 with the George Town Airport measurements for the same period.

1.2 FRM Non-Continuous Samplers

Prior to the sampling, the FRM equipment was leak tested and calibrated using a calibration kit specific to each unit. Each calibration kit was calibrated by the manufacturer and a calibration sheet was generated by the manufacturer with a calibration curve specific to each calibrator. GHD used a calibrated digital manometer to set the flow rate of the equipment to specifications and the flow rate was locked using set screws. Internal timing devices (chronometers) were used to record the time each FRM sampler was running in order to calculate the final volume sampled. The calibration procedures ensured the PM10 sampler was running at 40 cfm+/- 10% while the PUF sampler was running at 8 cfm+/- 10%. After initial calibration, calibration checks were performed monthly to ensure that the flow rate had not changed.

1.2.1 Chain of Custody

For each sample in the following section, chain of custody (COC) procedures were utilized from the point of transport to the laboratory. On each COC the following information was recorded at a minimum:

– Sample date
– Sample time
– Sampler name
– Required analyses
– Mode of transport
– Person who relinquished the samples for transport
– Person who received the samples by the laboratory

1.3 PM10/Metals

Each PM10 filter was weighed at ALS Labs and uniquely labelled. The filter was placed inside the filter holder by the sampler using nitrile gloves and secured in the housing. Field data sheets were used to record the unique identifier on each filter as well as all other pertinent information specific to each sample such as:

– Date
– Start time
– End time
– Chronometer starting value
– Chronometer ending value
– Laboratory sample number
– Field Sample Number with Sampler initials beginning at 01
– Weather Conditions
– Ambient temperature

At the end of the sample run, the filter was removed using nitrile gloves and placed into the unique envelope and the samples were stored in the container for shipment to ALS Labs in Burlington, Ontario, Canada. Pictures were taken of the sample prior to placing it in the envelope. Pictures were also taken of the sample data sheet. All laboratory hold times were adhered to for shipping and analysis of the samples. The field sampling and calibration forms for non-continuous sample collection are provided in Appendix C.

1.4 PUF Sampler

Each PUF/XAD cartridge and hexane rinsed filter was prepared by ALS Labs and uniquely labelled. Once received, the cartridges were placed inside a refrigerator in the container and kept cold. On the sampling day, the cartridge was

placed inside the housing by the sampler using nitrile gloves and secured in the housing. Field data sheets were used to record the unique identifier on each filter as well as all other pertinent information specific to each sample such as:

- Date
- Start time
- End time
- Chronometer starting value
- Chronometer ending value
- Laboratory sample number
- Field Sample Number with Sampler initials beginning at 01
- Weather Conditions
- Ambient temperature

At the end of the sample run, the cartridge was removed using nitrile gloves and placed into the unique packaging and the samples were stored in the container inside the refrigerator for shipment to ALS Labs in Burlington, Ontario, Canada. Pictures were taken of the sample prior to placing it in the envelope. Pictures were also taken of the sample data sheet. All laboratory hold times were adhered to for shipping and analysis of the samples. The field sampling and calibration forms for non-continuous sample collection are provided in Appendix C.

1.5 TO15 VOC from Summa Canisters

Each canister and 24hr mass flow controller (MFC) was cleaned/prepared and/or evacuated by ALS Labs and uniquely labelled. Once received, the summa canisters and MFCs were stored inside the container prior to use. When ready for sampling the MFC was attached to the canister and the canister/MFC was placed on the roof of the container and securely chained to the railing. At the start of sampling, the summa canister valve was opened and the vacuum at the beginning of the sample was recorded on a field data sheet. Field data sheets were used to record the unique identifier on each canister/MFC as well as all other pertinent information specific to each sample such as:

- Date
- Start time
- End time
- Vacuum starting value
- Vacuum ending value
- Laboratory canister/MFC number
- Field Sample Number with Sampler initials beginning at 01
- Weather Conditions
- Ambient temperature

At the end of the 24-hour sample run, the canister valve was closed and disassembled from the MFC and placed into a shipping box. The samples were stored in the container for shipment to ALS Labs in Burlington, Ontario, Canada. All laboratory hold times were adhered to for shipping and analysis of the samples by GC/MS. The field sampling and calibration forms for non-continuous sample collection are provided in Appendix C.

1.6 HCl/HF

The HCl/HF samples were collected from the exhaust of the CO monitor at approximately 800 ml/min using a mini-impinger and 0.1N H_2SO_4 reagent solution to capture the chloride and fluoride ions. Prior to sampling the impinger was rinsed with de-ionized water. After the rinse and prior to sampling, approximately 30 ml of the 0.1N H_2SO_4 reagent solution was added to the impinger and the impinger was placed in a holder. Teflon tubing was placed between the exhaust of the CO monitor and the flow rate of the CO monitor was recorded on a field data sheet.

Samples were allowed to run for 24-hours and the ending flow rate on the CO monitor was recorded. After the completion of the sample period, the samples were recovered by placing the reagent inside an amber glass sample jar. The impinger was rinsed with DI water and added to the sample jar and uniquely identified. Field data sheets were used to record the unique identifier on each impinger as well as all other pertinent information specific to each sample such as:

– Date
– Start time
– End time
– Flow rate starting value
– Flow rate ending value
– Field Sample Number with Sampler initials beginning at 01

The samples were stored in the container for shipment to ALS Labs in Burlington, Ontario, Canada. All laboratory hold times were adhered to for analysis of the samples.

1.7 Passive Samples

Passive sample media was prepared and shipped to the site on ice by Bureau Veritas (BV) labs. The following protocols were used on-site during the sampling at each location:

Deployment:

– The sample media was inspected for damage prior to use
– The sample media was deployed to their respective shelters
– The storage caps were replaced with the diffusive caps
– Sample information was recorded on field data sheet
– The media was exposed for required sampling period

Retrieval:

– Inspect the sample media for damage
– Replace the diffusive caps with the storage caps
– Record Sample information on the field data sheet
– Package exposed samples packs for shipment
– Send to the lab for analysis

The samples were stored in the refrigerator in the container for shipment on ice to BV Labs in Edmonton, Alberta, Canada. All laboratory hold times were adhered to for shipping and analysis of the samples.

1.8 Odour

The odour assessment specialist that completed the odour assessment survey has over 20 years experience at completing odour assessment surveys. Prior to the assessment survey the specialist was calibrated according to ASTM Special Technical Publication - STP 758 and EN 13725 using a triangular forced-choice olfactometer. The calibration ensured the assessment specialist was neither insensitive or oversensitive to the control odour (n-butanol).

Prior to odour assessment, the activated carbon and batteries in the Nasal Ranger were replaced. During the assessment the specialist ensured that the proper flow rate was being used to properly measure the field odour concentration.

1.9 Data Editing and Data Reduction

1.9.1 CEMs Results

Data editing and reduction was completed on the continuous data retrieved from Station 1 for NOx, NO, NO_2, SO_2 and PM2.5 data. The hourly data used to calculate the baseline concentrations for these parameters was edited by a person experienced with the workings of the analyzers and the calibration process. The edited data included deleting erroneous values created by the following reasons:

– Daily calibrations
– Monthly calibrations
– Analyzer zero drift
– Erroneous recorded data

Where values were edited for these reasons, the data was replaced by a blank cell and was not included in the calculation of the hourly baseline concentrations for these parameters.

1.9.2 Laboratory Results

Laboratory analytical data was edited to replace values that were not detected at the laboratory detection limits (DL) with the value of the detection limit for the purposes of this report. This is a conservative approach as the DL is generally substituted with half the DL for monitoring reports. In some cases, if a specific compound was not detected at the DL in any of the monitoring events, such as specific VOCs, they were not included in the reported results for calculation of baseline concentrations.

The Power of Commitment

Appendix C

Background NOx Emission Estimate

Appendix C Background NOx Emission Estimates Cayman Air Quality Assessment

1. Nearby Road Traffic

Motor vehicle tailpipe emissions are one of the major contributors to NO_x within an airshed. The following roads were identified as possible major contributors to NO_x, whose impact would have been captured at the background air monitoring stations:

– Godfrey Nixon Way
– Esterly Tibetts Hwy
– North Sound Road
– West Bay Road
– Lawerence Blvd
– Eastern Ave.

The US EPAs Latest Version of Motor Vehicle Emission Simulator (MOVES3) was used to generate the NO_x emission rates in terms of grams per vehicle kilometre travelled (g/VKT) for each vehicle category such as motorcycle, passenger car, transit bus, and single unit short-haul truck. MOVES3 is also capable of generating the emission rates for various vehicle speed bins under each vehicle category. Since MOVES3 is mainly designed for counties in the United States of America, the Monroe County of Florida was used as a representative for the Cayman Islands.

Based on their 2016 and 2019 study, the National Roads Authority (Cayman Islands) provided the Yearly Average Daily Traffic. According to Appendix 1 of the National Roads Authority of Cayman Islands' 2016–17 Annual Report, the primary arterial roads (Esterly Tibetts Highway, North Sound Road), secondary arterial roads (West Bay Road, Eastern Avenue), and Collector Roadways (Godfrey Nixon Way, Lawrence Blvd) experience an annual average growth rate of traffic of 4.46%, -1.04%, and 3.35%, respectively. The Traffic Speed Limits in Grand Cayman, available in the Regulations, 2016, Supplement No. 1, which was published in Extraordinary Gazette No. 15 on March 4, 2016, was used to determine the speed limit for each road.

The estimated road traffic emission rates for the year 2022, are summarized under Table A.1, and the roads were modelled as Line Area sources in AERMOD.

2. Caribbean Utilities Company

The Caribbean Utilities Company (CUC) is the major power utility in the vicinity of the Site. They have several heavy duty diesel generators, that are used to supply electricity to the local power grid. The list of generators used along with their location were provided in response to a ISWMS request for information by CUC to Dart.

According to Appendix A of the Caribbean Utilities Company, Ltd. 2022 Sustainability Report, the NO_x emissions in ktonnes for the years 2021, 2020, and 2019 were 8.47, 8.35, and 8.59, respectively. Assuming worst-case annual emissions of 8.59 ktonnes, the NO_x emission were distributed proportionately among the generators based on their power output. Note that this is a rough approximation as GHD did not have the utilization factors for the various generators used at CUC. The generators and their capacity along with the estimated NO_x emission rates are listed under Table A.2a. The location of the stacks associated with each generator, and their modelling parameters were estimated and summarized under Table A.2b.

3. Port activities – Cruise Ships

The Cayman Islands is considered as a great destination holiday spot by tourists, and Grand Cayman welcomes about 1.8 million cruise tourists per annum, bringing in revenue through tourism. The Port Authority of the Cayman Islands (Port) has four anchoring locations for Cruise Ships in the vicinity. Two of the anchoring positions are used for Dream Class Cruise ships, and the other two for Oasis Class Cruise ships. Based on the information provided in "Air Quality Report for EIA of The Cayman Islands Berthing Facility", June 1, 2015, the NO_x emission rates for these Cruise ships were determined. These Cruise Ships consume common residual oil as fuel for their main propulsion and auxiliary engines. The emissions from the ship maneuvering and hotelling activities were considered.

Emission estimation methodology for these ships is sourced from the "Current Methodologies in Preparing Mobile Source Port-Related Emission Inventories" Final Report - April 2009, prepared for US EPA by ICF International. The details of which are summarized in Table A.3a and Table A.3b. The stack parameters as suggested in "Generating an Hour-By-Hour Model-Ready Marine Emission Inventory" by Boulton et al, June 2008, US EPA 17th International Emission Inventory Conference were used in AERMOD.

4. Airport

The Owen Roberts International Airport (Airport) which is in the vicinity of the Site is considered to be a major source of NO_x as well. The Owen Roberts International Airport provided information on the 2019 Aircraft Movement. The Airline Movement Prediction from 2017 to 2022 was predicted to increase by 33% based on the Cayman Islands Airports Airport Master Plan 2032. Aircraft landing, taxing and idling, and takeoff make up a normal Landing Take Off (LTO) Cycle. A reasonable assumption that 75% of LTO emissions happen at ground level was assumed. As per the Owen Roberts International Airport Flight Schedule, aircraft activity in a day is between 6:00 AM And 11:00 PM, which leads to about 17-hours of aircraft emissions in a day.

The US EPA's Emission Factor for Aircraft was used to generate the emission rates, details of which are summarized in Table A.4. The Airport was modelled as a Polygon Area Source in AERMOD.

5. Medical Waste Incinerator

A medical waste incinerator is currently operating near the northern fenceline of the Site. The incinerator processes about 6,400 pounds of waste in one batch and the burn and cooldown cycle lasts about 24 hours. The site operates 2 batches per week to process the current inflow of medical waste. Reasonable estimates were made regarding the stack's height, diameter, and gas exit temperature. The estimated emission rate along with the modelling parameters are shown in Table A.5.

6. Cayman Spirits

There is a small-batch distillery, the Cayman Spirits that operate a boiler at its facility NO_x emissions from this boiler were estimated using emission factors for Small Boilers from Table 1.4-1 of the AP-42. Details of the boiler and estimated emission rates are summarized in Table A.6.

7. Central Laundry

A laundry facility, Central Laundry, operates one boiler at its facility. NO_x emissions from this boiler were estimated using emission factors for Small Boilers from Table 1.4-1 of the AP-42. Details of the boiler and estimated emission rates are summarized in Table A.6.

8. Asphalt and Cement Plants

A hot mix asphalt (HMA) plant is located west of the Site. Two main sources of NO_x emissions from this facility are estimated. The HMA baghouse estimates NO_x emissions using the maximum asphalt production capacity and the emission factors from AP-42 Table 11.1-5 for a No. 2 fuel iol-fired dryer, hot screens, and mixer. The second emission source is a hot oil heater for the asphalt storage tanks. AP-42 Table 1.3-1 is used to estimate the NO_x emission s from No. 4 fuel oil fired boilers. Details of the estimated emission rates and parameters are summarized in Table A.7.

9. Cement Plants

Three cement batching plants operate south of the Site. These plants are identified as Supermix, National Concrete, and Kirk Concrete. The NO_x emissions from diesel-fired generators are estimated using Table 3.3-1 of AP-42. Details of the generators and estimated emission rates are summarized in Table A.8.

Table C.1

Estimated NOx Emission Rates - Major Roads by ISWMS

Name of Road	Length (km)	Direction of Traffic	Annual Average Daily Traffic (2016)	Annual Average Daily Traffic (2019)	Annual Average Daily Traffic (2022)	Speed Limit (mph)	Motorcycle (%)	Motorcycle Count	Passenger Car (%)	Passenger Car Count	Transit Bus (%)	Transit Bus Count	Single Unit Short-haul Truck (%)	Single Unit Short-haul Truck Count	2022 NOx ER (g/s)

Notes:

(1) The Annual Average Daily Traffic was obtained from National Roads Authority (Cayman Islands), through their 2016 and 2019 study.
(2) As per Appendix 1 of the 2016/17 Annual Report for National Roads Authority of Cayman Islands, the Annual average growth rate of traffic for Primary Arterial Roadways (Esterly Tibetts Hwy, North Sound Road) is 4.46%, Secondary Arterial Roadways (West Bay Road, Eastern Ave) is -1.04%, and 3.35% for Collector Roadways (Godfrey Nixon Way, Lawrence Blvd).
(3) NOx emission factors were obtained from US EPA's software MOVES3.
(4) The Speed limit for each roadway was obtained from The Traffic (Speed Limits in Grand Cayman) Regulations, 2016. Supplement No. 1 published with Extraordinary Gazette No.15 dated 4th March, 2016.

Table C.2a

Estimated NOx Emission Rates
Generators within Caribbean Utilities Company, Ltd. (CUC)

Make and Model	Unit #	Unit Size (MW)	NOx Emission Rate (ktonne/year)	NOx Emission Rate (g/s)
Caterpillar 3616	19	4	0.21	6.77
Caterpillar 3616	20	4	0.21	6.77

Man B&W 18V 48/60	31	18.5	0.99	31.31
Steam Turbine	28	2.6	0.14	4.40

Notes:

(1) The Make and Model, Unit number, and Unit Size were provided through correspondance with Caribbean Utilities Company, Ltd.
(2) As per the Caribbean Utilities Company, Ltd. 2022 Sustainability Report, Appendix A, for the years 2021, 2020, and 2019 the installed generation capacity was 160.95 MW.
(3) As per the Caribbean Utilities Company, Ltd. 2022 Sustainability Report, Appendix A, for the years 2021, 2020, and 2019 the NOx emissions in ktonnes were 8.47, 8.35, and 8.59 respectively.
(4) Assuming worst case emisisons of 8.59 ktonnes per year, and dividing the emissions proportionally between the generators based on their capacity.
(5) Unit 19 and 20, are not currently operational, hence not considered for the dispersion model.

Table C.2b

CUC Generators and their Associated Stack Parameters used for Dispersion Modelling

Generators Make and Model	Generator Unit #	Stack ID	Stack UTM X Coordinate (m)	Stack UTM Y Coordinate (m)	Exhaust Flow rate [6] (m^3/s)	Gas Exit Temperature [6] (°C)	Stack Tip Inside Diameter (m)	Stack Tip Release Height (m)

Caterpillar 3516C, Caterpillar	41, 42, 43, 44	CUC10	461797.26	2134277.39	31.83	490.70	2.00	42.40

Notes:

(1) The location of the Generators were provided through correspondance with Caribbean Utilities Company, Ltd.
(2) The location of stacks associated with the generators, along with their stack tip inside diamter was approximately determined using Google Earth satelite imagery.
(3) The stack tip release height was assumed to be 42.4 m for all the stacks considered within CUC, based on the technical data from a brochure created by Burmeister & Wain Scandinavian Contractor for CUC as part of their ten Year Starategic Alliance Success.
(4) For generators that did not have the Exhaust Flow rate provided in their technical spec sheets, the exhaust flow rate was extrapolated based on generator capacity.
(5) For generators that did not have gas exit temperature, it was assumed to be 480 °C.
(6) The Exhaust Flow rate and Gas Exit temperature were obtained from technical spec sheets of the Generator.

Table C.3a

Estimated NOx Emission Rates
Cruise Ships (Dream Class) Hoteling by the Port

Formulas:
E(g) = P(kW)*LF(%)*A(hour)*EF(g/kWh)

Where,	E	= Emissions (grams)
	P	= Maximum Continuous Rating Power (kW)
	LF	= Load Factor (percent of vessel's total power)
	A	= Activity Duration (hour)
	EF	= Emission Factor (g/kWh)

LF = (AS/MS)^3

Where,	LF	= Load Factor (percent of vessel's total power)
	AS	= Actual Speed (knots)
	MS	= Maximum Speed (knots)

Based on "Air Quality Report For EIA of The Cayman Islands Berthing Facility", June 1, 2015:

Example Cruise ship (Dream Class Vessel):
The Carnival Dream

Maximum Continuous Power Rating
75,600 kW

Fuel used my main propulsion engine:
Common Residual Oil

Main propulsion engine were assumed to be medium speed, with a range of 130 RPM to 1,400 RPM.

It is assumed that the onboard garbage incinerators do not operate while the ships are hoteling by the port.

The following duration for each Cruise ship activity is assumed within a 24 hour period:

Maneuvering	1 hour
Hoteling	8 hour

No "cold ironing" (ship powered from shore) nor over-nighting of Cruise ships were assumed.

The engine load factor while hoteling is assumed to be same was while the cruise ship is maneuvering.

Within the ports domain (25 nautical miles), the Maneuvering speed of each Cruise ship is 8 knots.

An adjustment factor of 0.7565 was used for NOx emission factors, as suggested in Table 2-12 of reference document cited under Note 1.

NOx emission factors begin to increase due to inefficient engine operations when engine load falls below 20% (1). The following adjustment factors were used for these load factors from Table 2-15 of reference document cited under Note 1.

Load factor of 19%	1.01
Load factor of 6%	1.60

Cruise Ship Activity	Load Factor (%)	Activity Duration (hour)	Emission Factor (g/kWh)	Adjustment Factor	Adjusted Emission Factor (g/kWh)	NOx Emissions (g)
Maneuvering	6%	1	14	1.60	22.400	93622.86
Hoteling	6%	8	14	1.60	22.400	748982.86

Total NOx emisisons per Cruise Ship over a 9 hour period (g) = 842605.71

NOx emission rate per cruise ship (g/s) = 26.006

Stack Parameters[2]	Value	Units
Stack Diameter	0.8	m
Gas Exit Velocity	25	m/s
Gas Exit Temp	282	° C
Stack Height	20	m

Notes:

(1) Emission estimation methodology for these ships is sourced from the "Current Methodologies in Preparing Mobile Source Port-Related Emission Inventories" Final Report - April 2009, prepared for US EPA by ICF International.
(2) "Generating an Hour-By-Hour Model-Ready Marine Emission Inventory" by Boulton et al, June 2008, US EPA 17th International Emission Inventory Conference.
https://www3.epa.gov/ttnchie1/conference/ei17/session6/boulton_pres.pdf

Table C.3b

Estimated NOx Emission Rates
Cruise Ships (Oasis Class) Hoteling by the Port

Formulas:

*E(g) = P(kW)*LF(%)*A(hour)*EF(g/kWh)*

Where,	E	= Emissions (grams)
	P	= Maximum Continuous Rating Power (kW)
	LF	= Load Factor (percent of vessel's total power)
	A	= Activity Duration (hour)
	EF	= Emission Factor (g/kWh)

LF = (AS/MS)^3

Where,	LF	= Load Factor (percent of vessel's total power)
	AS	= Actual Speed (knots)
	MS	= Maximum Speed (knots)

Based on "Air Quality Report For EIA of The Cayman Islands Berthing Facility", June 1, 2015:

Example Cruise ship (Oasis Class Vessel):

Oasis of the Seas

Maximum Continuous Power Rating:

Main Propulsion Engine	82,000	kW
Auxilary Engine	115920	kW

Fuel used my main propulsion engine:

Common Residual Oil

Main propulsion enginer were assumed to be medium speed, with a range of 130 RPM to 1,400 RPM.

It is assumed that the onboard garbage incinerators do not operate while the ships are hoteling by the port.

Within the ports domain (25 nautical miles), the following duration for each Cruise ship activity is assumed within a 24 hour period:

Maneuvering	1	hour
Hoteling	8	hour

No "cold ironing" (ship powered from shore) nor over-nighting of Cruise ships were assumed.

The engine load factor while hoteling is assumed to be same was while the cruise ship is maneuvering.

Within the ports domain (25 nautical miles), the Maneuvering speed of each Cruise ship is 8 knots.

An adjustment factor of 0.7478 was used for NOx emission factors, as suggested in Table 2-12 of reference document cited under Note 1.

NOx emission factors begin to increase due to inefficient engine operations when engine load falls below 20% (1). The following adjustment factors were used for these load factors:

Load factor of 19%	1.01
Load factor of 6%	1.60

Propulsion Engine Emissions

Cruise Ship Activity	Load Factor (%)	Activity Duration (hour)	Emission Factor (g/kWh)	Adjustment Factor	Adjusted Emission Factor (g/kWh)	NOx Emissions (g)
Maneuvering	6%	1	14	1.60	22.400	101548.60
Hoteling	6%	8	14	1.60	22.400	812388.81

Auxilary Engine Emissions

Cruise Ship Activity	Load Factor (%)	Activity Duration (hour)	Emission Factor (g/kWh)	Adjustment Factor	Adjusted Emission Factor (g/kWh)	NOx Emissions (g)
Maneuvering	80%	1	14.7	0.7478	10.993	1019415.32
Hoteling	64%	8	14.7	0.7478	10.993	6524258.03

Total NOx emisisons per Cruise Ship over a 9 hour period (g) = 8457610.77

NOx emission rate per cruise ship (g/s) = 261.037

Stack Parameters[3]	Value	Units
Stack Diameter	0.8	m
Gas Exit Velocity	25	m/s
Gas Exit Temp	282	° C
Stack Height	20	m

Notes:

(1) Emission estimate formula is sourced from the "Current Methodologies in Preparing Mobile Source Port-Related Emission Inventories" Final Report - April 2009, prepared for US EPA by ICF International.
(2) Oasis of the Seas onboard engine details were acquired from the vessel register https://vesselregister.dnv.com/vesselregister/details/27091
(3) "Generating an Hour-By-Hour Model-Ready Marine Emission Inventory" by Boulton et al, June 2008, US EPA 17th International Emission Inventory Conference. https://www3.epa.gov/ttnchie1/conference/ei17/session6/boulton_pres.pdf

Table C.4

Estimated NOx Emission Rates
Aircraft Activity at the Owen Roberts International Airport

Aircraft Type	Aircraft Movement		NOx Emission Factor	NOx Emission Rate			
	2019	2022	(Tons/LTO)	(Tons/year)	(Tonne/Year)	(g/year)	(g/s)
Jet	17571	23370	9.29E-03	1.63E+02	1.48E+02	1.48E+08	6.61E+00
Piston	484	644	3.25E-05	1.57E-02	1.42E-02	1.42E+04	6.38E-04
Turbine	8988	11955	1.62E-04	1.45E+00	1.32E+00	1.32E+06	5.90E-02

Notes:

(1) The 2019 Aircraft Movement was obtained from Owen Roberts International Airport.
(2) Based on the Cayman Islands Airports Airport Master Plan 2032, the Aircraft Movement Forecast was estimated to be an increase of 33% from the year 2017 to 2022.
(3) A typical Landing Take Off (LTO) Cycle consists of Aircraft Landing, Taxing and Idling, and finally Take Off.
(4) Conservatively assuming 75% of LTO emission occur at ground level.
(5) The Emission Factor for Aircrafts was obtained from US EPA in the link provided below
https://www.epa.gov/sites/default/files/2016-04/documents/nei2014_genericef_table.pdf
(6) As per the Owen Roberts International Airport Flight Schedule, aircraft activity in a day is between 6:00 AM and 11:00PM. Aircraft emissions occur 17 hours in a day.
https://www.caymanairports.com/upimages/commonfile/1449917851FLIGHT_SCHEDULE_Updated_on_Jun_24_2013.pdf

Table C.5

Estimated Emission Rates - Medical Waste Incinerator of ISWMS

Medical Waste Incinerated per Batch (Mg)	NOx Emission Factor (kg/Mg)	CO Emission Factor (kg/Mg)	NOxCO (kg)	Daily CO Emission Rate (g/s)	NOx Emission Per Batch (kg)	Daily NOx Emission Rate (g/s)
2.90	1.58	0.15	0.435	0.012	4.587	0.127

Stack Parameters

	Stack UTM X Coordinate (m)	Stack UTM Y Coordinate (m)	Exhaust Flow rate (m^3/s)	Gas Exit Temperature (°C)	Stack Tip Inside Diameter (m)	Stack Tip Release Height (m)
Existing Location	460795.11	2135424.3	0.6	1000	0.75	10
Future Location	460752.73	2135046.5	0.6	1000	0.75	10

Notes:

(1) As per information received by DART from DEH on 2 Nov 2022, the Medical Waste Incinerator, handles 6,400 lb of medical waste per batch. There are two batch handled a week, and each batch lasts 10 hours. The Secondary chamber operates at 1038 °C.
(2) Reasonable assumptions were made for stack height, stack diameter, stack gas exit temperature since there was no available information.
(4) The stack flow rate is assumed to be 0.6 m^3/s, which is the ideal design consideration as per a guidance document by Central Pollution Control Board of India for medical waste incinerators.
(5) Emission factors for Modular Starved Air Combustors from Table 2.1-9 of the AP-42 was used.

Table C.6

Estimated NOx Emission Rates - Boiler at Cayman Spirits and Central Laundry

Make and Model of boiler	Boiler Heat Input (Btu/hr)	Natural Gas Consumption (Scf/hr)	NOx Emission Factor (lb/10^6 scf)	NOx Emission Rate (lb/hr)	NOx Emission Rate (g/s)
Columbia 50 MPH (Cayman Spirits)	2,100,000	2058.824	100	0.206	0.026
Cleaver Brooks CBLE.700.300 (Central Laundry)	10,045,000	9848.039	100	0.985	0.124

Stack Parameters

Location	Stack UTM X Coordinate (m)	Stack UTM Y Coordinate (m)	Exhaust Flow rate (m^3/s)	Gas Exit Temperature (°C)	Stack Tip Inside Diameter (m)	Stack Tip Release Height (m)
Cayman Spirits	461008.88	2134244.49	0.176	200	0.5	11
Central Laundry	461046.99	2135176.54	0.843	200	0.5	7

Notes:

(1) Emission factors for Small Boilers from Table 1.4-1 of the AP-42 was used.
(2) Reasonable assumptions were made for the exhaust flow rate, stack diameter, and stack temperature since there was no available information.

Table C.7

Estimated NOx Emission Rates - Hot Mix Asphalt (HMA) Plant

Oil Fired Dryer emission rates throught HMA Baghouse

HMA Manufactured per Day (Mg)	NOx Emission Factor[1] (kg/Mg)	NOx Emission (kg/day)	NOx Emission Rate (g/s)
725.75	0.06	43.545	1.008

Emission rates of Hot Oil Heater for Asphalt storage tanks

Fuel Consumption (MMBTU/hr)	NOx Emission Factor[2] (lb/10^3 gal)	NOx Emission (lb/hr)	NOx Emission Rate (g/s)
3.00	20	0.405	0.051

Stack Parameters

Equipment	Stack UTM X Coordinate (m)	Stack UTM Y Coordinate (m)	Exhaust Flow rate (m^3/s)	Gas Exit Temperature (°C)	Stack Tip Inside Diameter (m)	Stack Tip Release Height (m)
Baghouse	461193.25	2134903.93	31.00	110	1.3	9
Asphalt Tank Heater	461172.86	2134899.34	0.60	200	0.3	3

Notes:

(1) Emission factors from Table 11.1-5 of AP-42 for Batch Mix Hot Asphalt Plant, using No.2 fuel oil-fired dryer, hot screens, and mixer was used.
(2) Emission factors from Table 1.3-1 of AP-42 for No. 4 oil fired boilers <100 MMBtu/hr.
(3) A heating value of 148100 Btu/gal was used for No. 4 Fuel Oil.
(4) A 12 hour operational period per day was assumed.
(5) The heater for the Asphalt storage tanks are expected to run 24 hours a day.
(6) A production capacity of 725.75 tonne per day was used for the Hot Mix Asphalt plant as conveyed by Dart in their email dated April 12, 2023.
(7) Reasonable assumptions were made for the Crusher Engine power rating, and fuel consumption rate for the hot oil heater of Asphalt Storage tanks.
(8) Stack parameters were extracted from similar Hot Asphalt Mix sites.

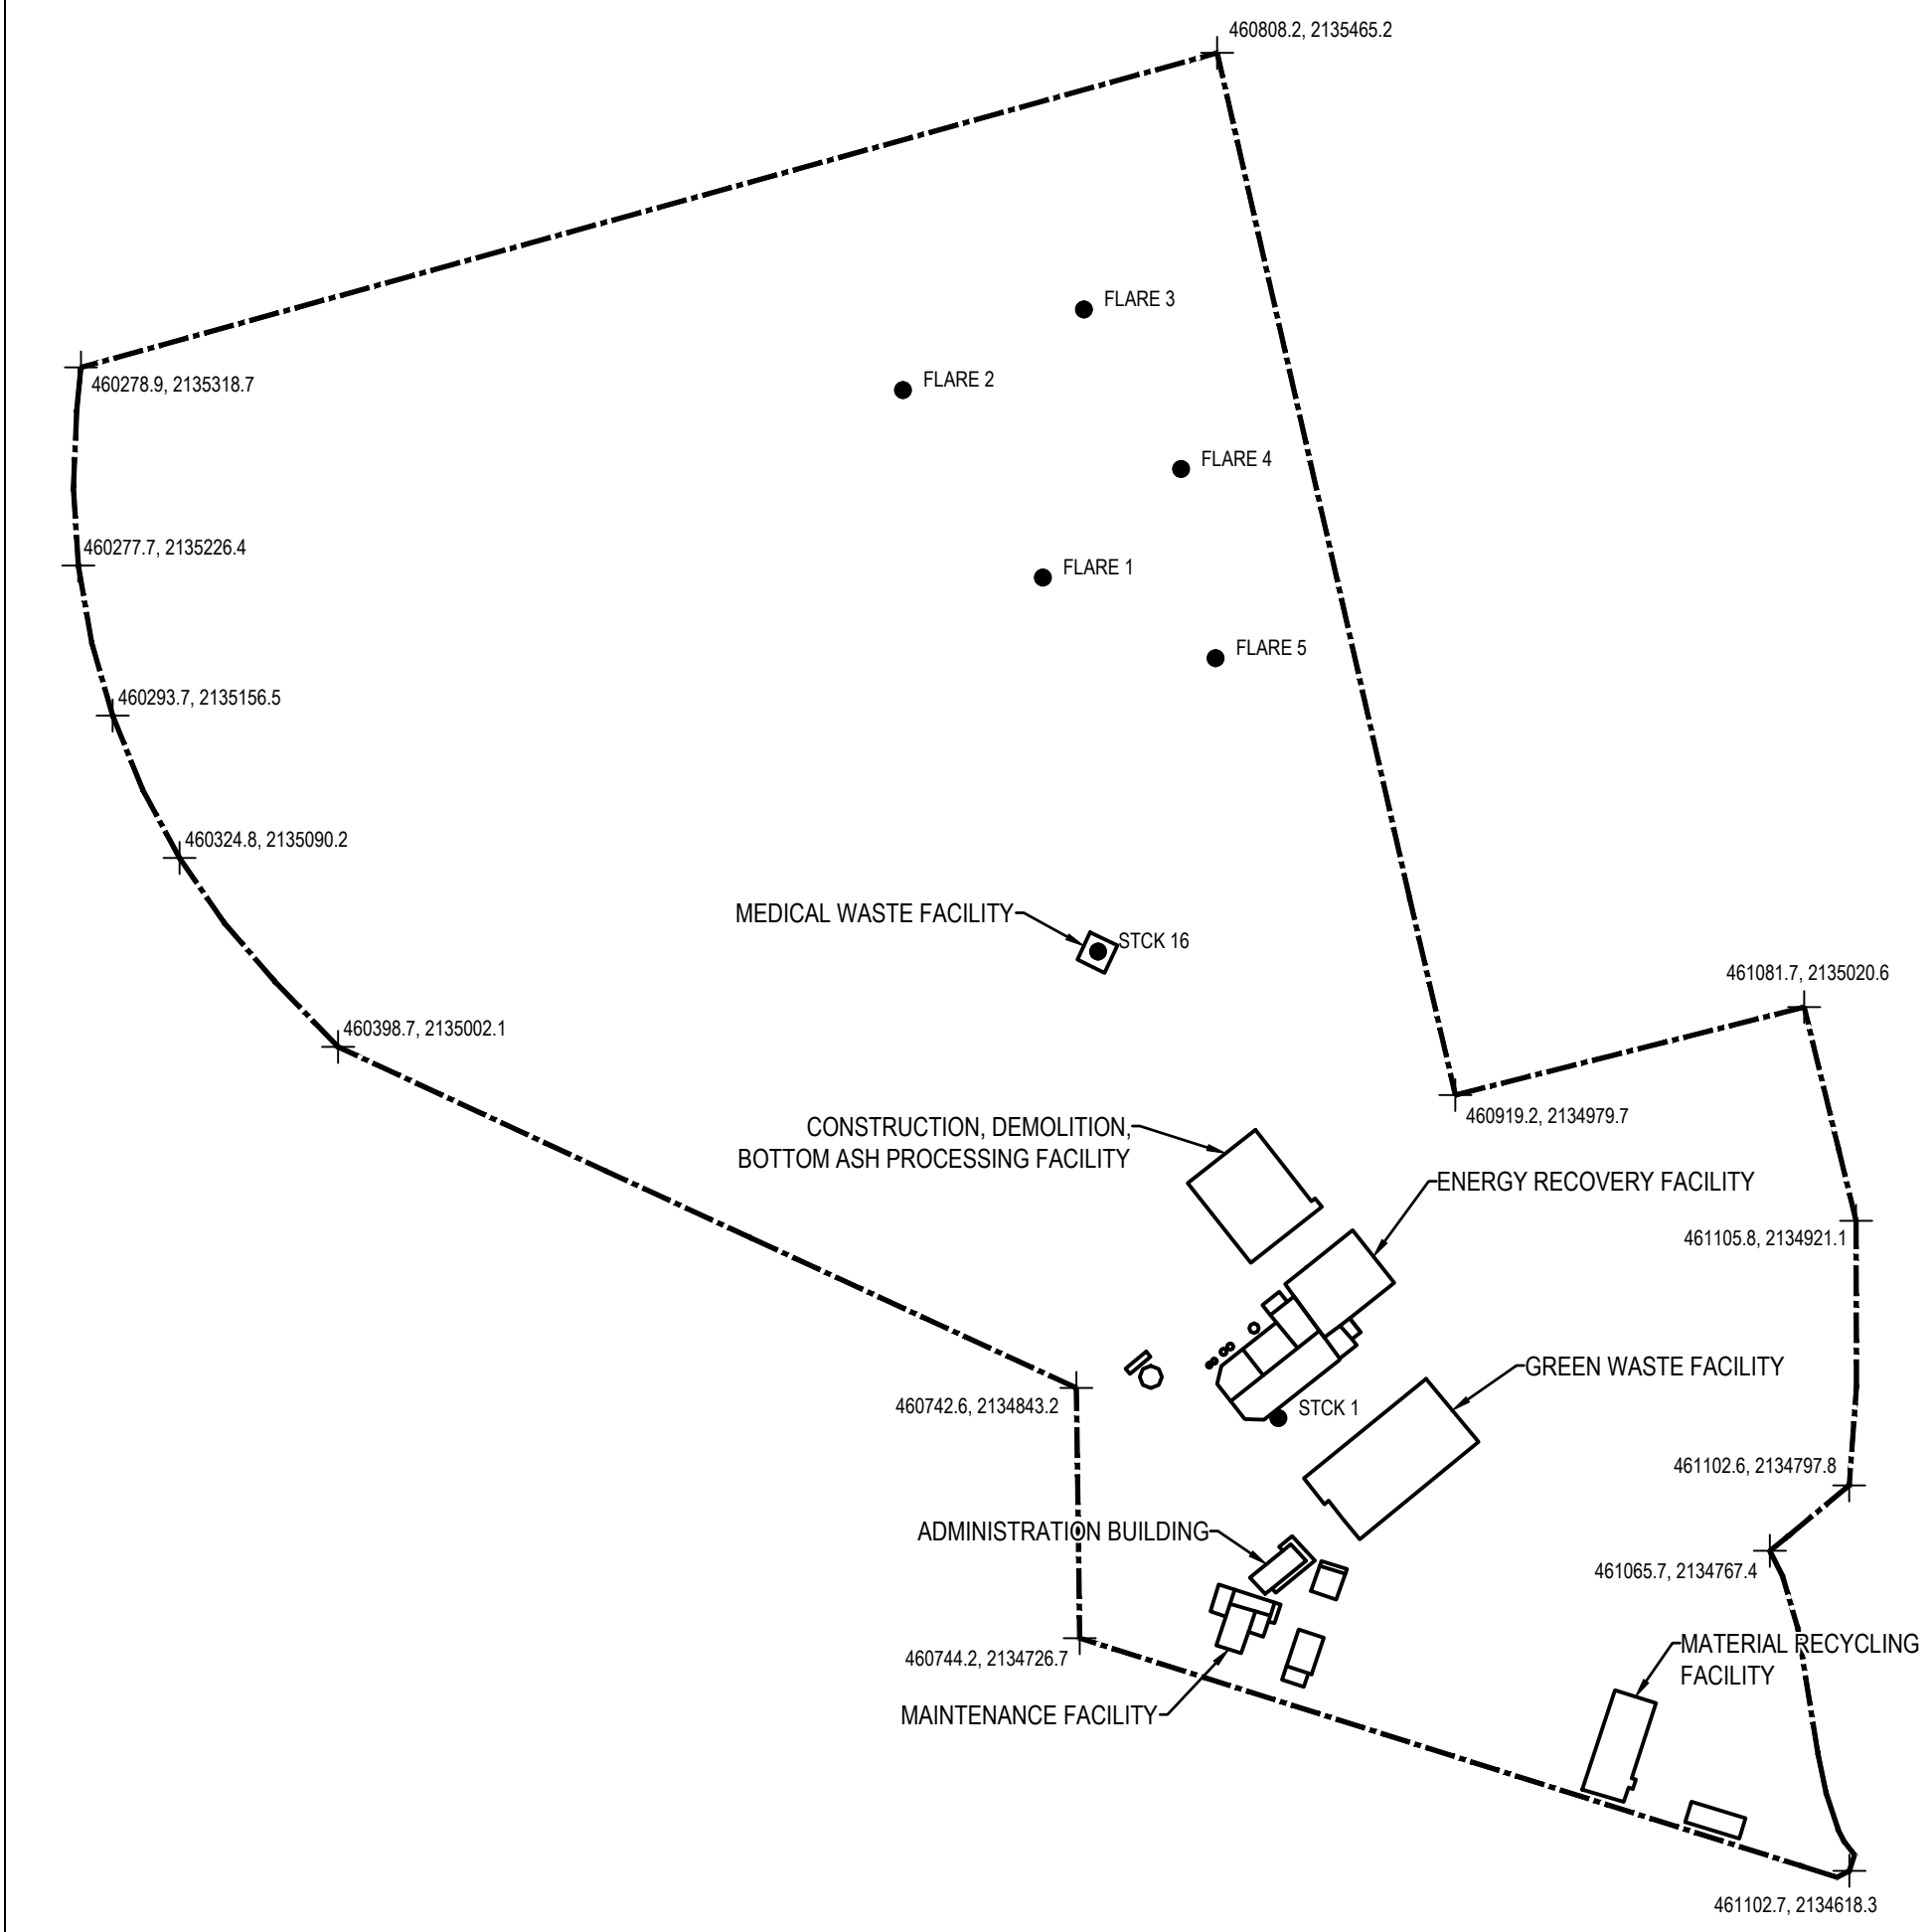
Table C.8

Estimated NOx Emission Rates - Concrete Batch Mixer Plants

Main Diesel-fired Generator

Location	Power Rating of Engine Used [1] (kW)	NOx Emission Factor[2] (kg/kW-hr)	NOx Emission (kg/hr)	NOx Emission Rate (g/s)
National Concrete	150.00	0.019	2.827	0.065
Supermix	150.00	0.019	2.827	0.065
Kirk Concrete	150.00	0.019	2.827	0.065

Stack Parameters



Location	Stack UTM X Coordinate (m)	Stack UTM Y Coordinate (m)	Exhaust Flow rate (m^3/s)	Gas Exit Temperature (°C)	Stack Tip Inside Diameter (m)	Stack Tip Release Height (m)
National Concrete	461610.87	2134392.4	0.5	455	0.13	6
Supermix	461164.03	2134557.94	0.5	455	0.13	6
Kirk Concrete	461180.98	2134375.93	0.5	455	0.13	6

Notes:

(1) Engine power ratings are engineering estimates
(2) Emission factors from Table 3.3-1 of AP-42 for diesel industrial engines.

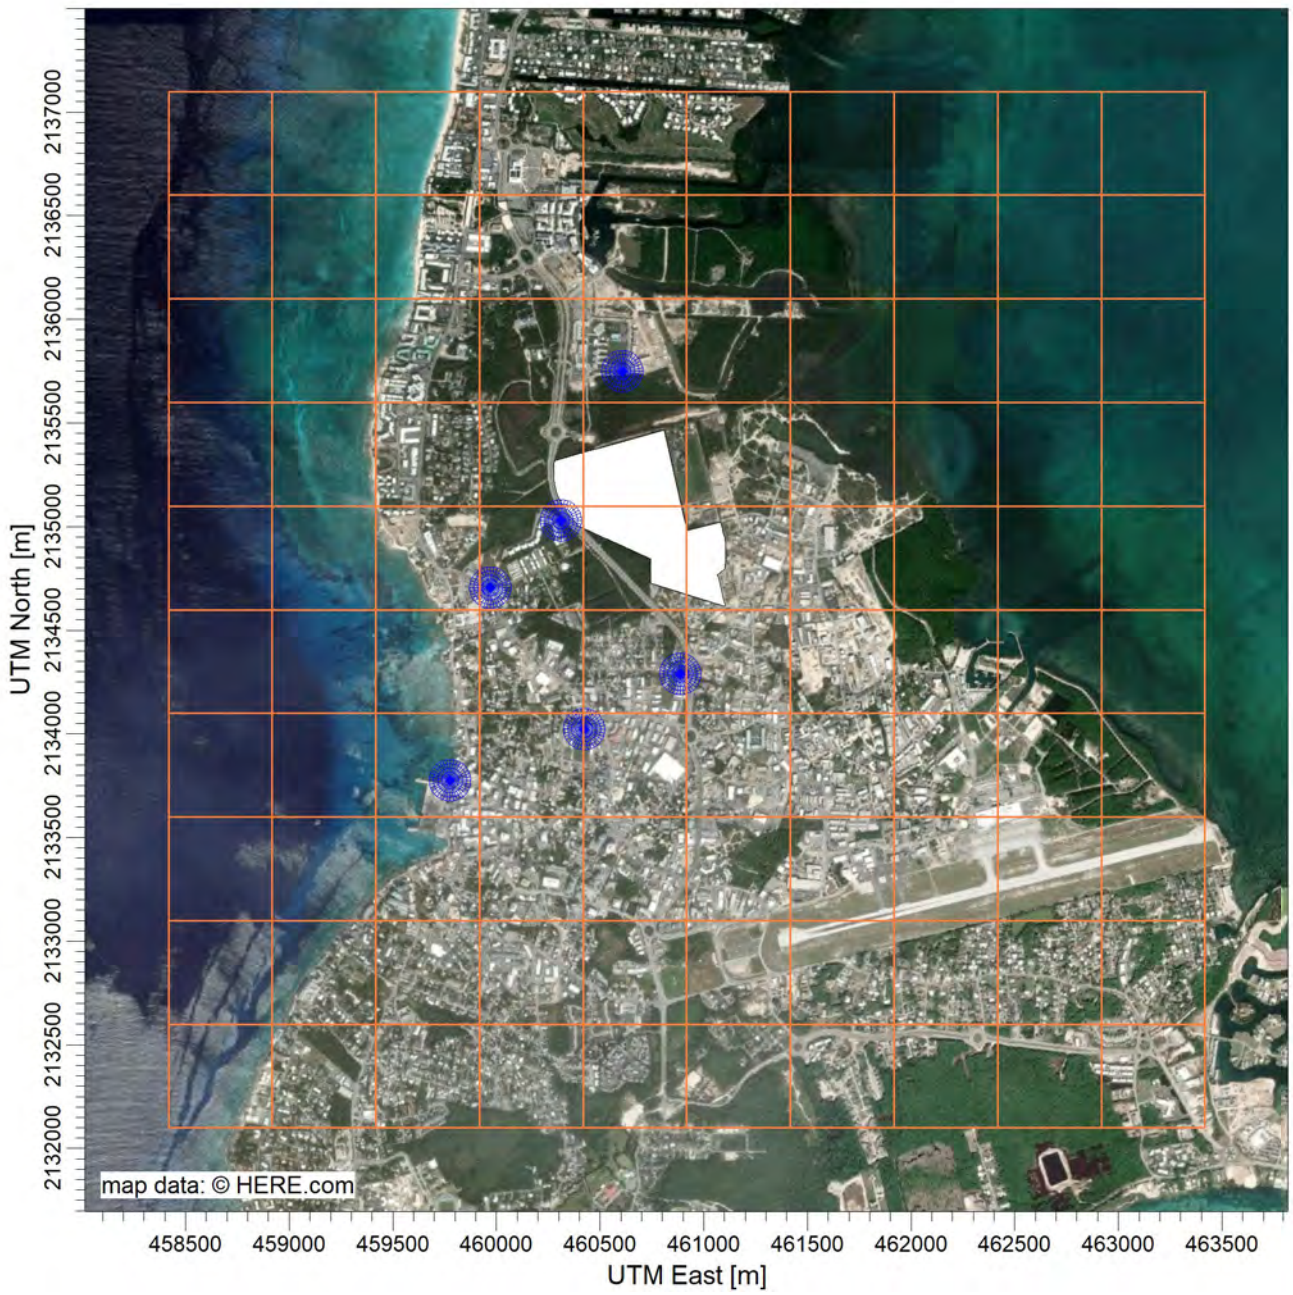
Waste Incinerator Manufacturer In-stack Concentration Guarantees

Substance	Base unit	Daily average	Half-hourly avg.		10 min. average	Sampling period *1
			100%	97%		
Total dust	mg/m^3 STP, dry, 11% O2	5	30	10	-	-
Hydrogen chloride (HCl)	mg/m^3 STP, dry, 11% O2	6	60	10	-	-
Hydrogen fluoride (HF)	mg/m^3 STP, dry, 11% O2	1 *2	4	2	-	1 *2
Sulphur dioxide (SO_2)	mg/m^3 STP, dry, 11% O2	30	200	50	-	-
Gaseous + vaporous organic substances, expressed as total organic carbon (TOC)	mg/m^3 STP, dry, 11% O2	10	20	10	-	-
Carbon monoxide (CO)	mg/m^3 STP, dry, 11% O2	50	100	-	150	-
Nitrogen monoxide (NO) + nitrogen dioxide (NO_2) expressed as NO_2	mg/m^3 STP, dry, 11% O2	120	400	200	-	-
Ammonia (NH_3)	mg/m^3 STP, dry, 11% O2	10	-	-	-	-
Cadmium + Thallium (Cd + Tl)	$\mu g/m^3$ STP, dry, 11% O2	-	-	-	-	20
Mercury (Hg) + its compounds	$\mu g/m^3$ STP, dry, 11% O2	20 *2	35	-	-	20 *2
Σ heavy metals incl. comp. (Sb + As + Pb + Cr + Co + Cu + Mn + Ni + V)	$\mu g/m^3$ STP, dry, 11% O2	-	-	-	-	300
Dioxins and furans (PCDD/F)	ng/m^3 STP, dry, 11% O2	-	-	-	-	0.04
PCDD/F and dioxin-like PCB's	ng/m^3 STP, dry, 11% O2	-	-	-	-	0.06



*1 The following sampling periods shall be applied to all substances which are only measured during a specific period:
a) For PCDD/F and PCB's: Sampling period = 6 - 8 hours
b) For all other pollutants: Sampling period = min. 30 min. → Average value of 3 consecutive measurements

*2 According to the new BREF regulation (published 03.12.2019), emission limit values for hydrogen fluoride (HF) and mercury (Hg) can be defined either as daily average values or as average values over a sampling period.

Contents

1. Introduction 1
1.1 Purpose of this Report 1
1.2 Overview of the Proposed Development 1
1.2.1 Key Features 2
1.2.2 Timeframes 2
1.3 Study Areas and Assessment Boundaries 2
1.3.1 Spatial Boundaries 2
1.3.1.1 Site Study Area (SSA) (or "Project Footprint") 2
1.3.1.2 Local Study Area (LSA) 3
1.3.1.3 Regional Study Area (RSA) 3
1.3.2 Temporal Boundaries 4
1.3.3 Technical Boundaries 4
1.3.4 Sensitive Receptor Locations – ISWMS Development 5
1.4 Existing Noise & Vibration Environment 6
1.4.1 Existing Site and Surroundings 7
1.5 Baseline Noise Monitoring Results 8
1.5.1 Baseline Noise Monitoring Systems 8
1.5.2 Duration of Baseline Noise Monitoring 8
1.5.3 Baseline Noise Monitoring Results 9
2. Applicable Standards and Guidelines 10
2.1 Assessment Criteria for Operational Noise Effects 10
2.2 Assessment of Operational Traffic Noise Effects 12
2.3 Assessment Criteria for Construction Noise Effects 14
2.4 Assessment Criteria for Construction Road Traffic Noise 16
2.5 Assessment Criteria for Construction Vibration 17
3. Assessment Methodology 17
3.1 Noise Modelling and Prediction Methodology 18
4. Noise Impact Assessment 20
4.1 Design Assumptions and Mitigation Summary 20
4.1.1 Energy Recovery Facility (ERF) 20
4.1.1.1 Principal Noise Sources with Specific Noise Mitigation Measures Incorporated into the Design 21
4.1.1.2 ERF Building Shell and Penetrations 22
4.1.1.3 ERF Main Stack Outlet (and ID Fan) 22
4.1.1.4 Turbine Hall 22
4.1.1.5 ERF Waste Reception Area/Tipping Hall 23
4.1.1.6 Noise Associated with Operational ERF Emergency Steam Relief and Commissioning Steam Purging 23
4.1.2 Bottom Ash Handling Building (BAH) 24
4.1.3 Fire Pump Building (FPB) 24
4.1.4 Green Waste Facility (GWF) 24
4.1.5 Materials Recycling Facility Building (MRF) 25

Contents

4.2 Noise Source Summary 26
4.2.1 Sitewide Outdoor Truck and Heavy Equipment Volumes 27
4.2.2 Energy Recovery Facility (ERF) 28
4.2.3 Site Weighbridges 28
4.2.4 Green Waste Processing Facility 28
4.2.5 Construction and Demolition Waste Processing Facility 29
4.2.6 Bottom Ash Processing Facility 29
4.2.7 Abandoned and End-of-Life / Scrap Metal Processing Facility 29
4.2.8 Medical Waste Facility 29
4.2.9 Materials Recycling Facility 29
4.2.10 Household Waste Recycling Centre 29
4.2.11 Landfill Gas Facility 30
4.2.12 Admin Building 30
4.2.13 Maintenance Building 30
4.2.14 Future Phase 2 Residual Waste Landfill Operations 30
4.2.15 Construction Noise Source Summary 30
4.3 Assessment of Effects 32
4.3.1 Impact of the Operations Associated with the ISWMS 32
4.3.2 Off-Site Vehicle Movements due to Operations of the ISWMS 32
4.3.3 Noise Impact Assessment - BS4142 Assessment 33
4.3.3.1 Rating level 33
4.3.3.2 Comparison of the Background Sound and Rating Levels 34
4.3.3.3 BS4142 Context Assessment 36
4.3.3.4 BS8233 Context Assessment 40
4.3.3.5 Summary of BS4142 Assessment 42
4.3.4 Construction Noise Assessment 42
4.3.5 Construction Traffic Noise Assessment 43

5. Noise Mitigation Measures 44
5.1 Noise from the ISWMS Operations 44
5.2 Noise from Construction Phase Activities 45
5.3 Residual Effects 46
5.4 Inter-Related Effects 46

6. Conclusions 47
6.1 Noise from the Proposed ISWMS Operations 47
6.2 ISWMS Generated Road Traffic Noise 47
6.3 Noise and Vibration from Construction Phase Activities 48
6.4 Noise from Construction Traffic 48
6.5 Mitigation Measures 48

1. Introduction

1.1 Purpose of this Report

ReGen (‘the proponent') is seeking approval for the development of a proposed Integrated Solid Waste Management System (ISWMS) in the Cayman Islands (‘the project'). Construction and operation of the Project is proposed to allow the existing landfill in George Town to be closed, remediated, and replaced with an integrated waste management philosophy based on the core principles of the international waste hierarchy.

This report presents the Noise and Vibration Impact Assessment (NVIA) prepared to support the Environmental Impact Assessment (EIA) for the project. It has been prepared to address the noise and vibration requirements of the Final Terms of Reference (ToR) prepared by the proponent.

This NVIA reports the likely effects of the Proposed Development in terms of noise and vibration in the context of the Site and surrounding area, and whether these would be deemed to be significant. In particular it considers the likely effects of noise and vibration from the Proposed Development and its impact on nearby receptors through the construction and operational phases of the project.

In line with ToR for project, the objectives for the NVIA are to evaluate that the direct and indirect significant effects of a proposed development which are to be identified, described and assessed. Unwanted noise & vibration are known to have an adverse impact on health and quality of life. The activities proposed during the construction and operational phases of the ISWMS have the potential to result in a measurable increase to levels of noise and vibration in the vicinity of the proposed development, and therefore a potential for significant effect on health and quality of life and so these activities have been assessed in detail to confirm potential impacts as part of the EIA process.

The NVIA has been informed by the outcomes of stakeholder consultation conducted by the proponent to date, which sought input from key project-affected stakeholders and members of the broader local community. It also includes consideration of the results of other technical chapters prepared for the EIA, including Traffic and Transport (Chapter 13).

1.2 Overview of the Proposed Development

Each year, approximately 115,000 tons of solid waste is produced in the Cayman Islands, with the overwhelming majority of the material presently being managed by the George Town landfill (GTLF). This landfill capacity is, however, finite and in accordance with the provisions of both the National Solid Waste Management Strategy for the Cayman Islands (2016) and the National Planning Framework (draft for public consultation) (2018), the ToR has been prepared in relation to the proposed development of a replacement ISWMS for the Cayman Islands.

The proposed ISWMS site is located to the north of central George Town towards the western coast of Grand Cayman, immediately south-west of the existing GTLF. The proposed ISWMS is a multi-facility development, including an energy recovery facility (ERF) and supporting non-ERF waste processing, treatment, and disposal facilities. Construction and operation of the ISWMS would allow the existing landfills in George Town, Cayman Brac and Little Cayman to be closed and remediated.

Section 5.7.8 of ToR states – ‘The development also includes the construction of facilities on Grand Cayman’s Sister Islands namely, Little Cayman and Cayman Brac. This assessment includes the construction phases of these facilities – the operational phases of the Sister Island facilities will be managed by the Department of Environmental Health and therefore the assessment of this not covered in this report.’

The NVIA has been prepared considerate of the ToR and an evaluation of the operational phases of the Sister Island (SI) facilities was not included in this assessment. It is expected that a noise assessment for SI facilities will be

conducted when plan of facilities in the Sister Islands is finalized with Cayman Islands Government or similar responsible agencies.

1.2.1 Key Features

The proposed ISWMS development consists of various new waste management facilities. The various components of the ISWMS subject to assessment in this NVIA are as follows:

The Study Area considered within this report is principally focussed on the entire footprint of the ISWMS. GHD understand that the ISWMS will include the following elements:

– Energy Recovery Facility (ERF)
– Non-Energy Recovery Facilities:
  - Site weighbridges
  - Green Waste Processing Facility
  - Construction and Demolition Waste Processing Facility
  - Bottom Ash Processing Facility
  - Abandoned and End-of-Life / Scrap Metal Processing Facility
  - Medical Waste Facility
  - Materials Recycling Facility
  - Household Waste Recycling Centre
  - Landfill Gas Facility
  - Residual Waste Landfill
– Ancillary Facilities:
  - Admin Building
  - Maintenance Building

The design life of the new facilities is 25 years.

A complete description of each of the project elements described above is provided in Chapter 4 (Proposed Project and Overview of Concerns and Constraints) of the EIA.

1.2.2 Timeframes

Construction for the proposed ISWMS development would commence in 2024, with completion planned in 2027 (subject to final review and confirmation).

1.3 Study Areas and Assessment Boundaries

1.3.1 Spatial Boundaries

The following spatial boundaries apply to Noise and Vibration:

1.3.1.1 Site Study Area (SSA) (or "Project Footprint")

The SSA encompasses the land area directly disturbed by Project construction activities, including associated physical works and activities. The proposed ISWMS site is located to the north of central George Town towards the western coast of Grand Cayman, immediately south-west of the existing GTLF as shown in Figure 1. Access to the site will be via Seymour Drive from the south.

1.3.1.2 Local Study Area (LSA)

The Noise and Vibration LSA encompasses all lands within a 1,000 m radius of the SSA boundaries as shown in Figure 1. The maximum noise impacts are expected to occur at the property line and within 500 m of the SSA. The LSA has been defined as double this distance to conservatively assess all likely and lessor noise impacts in **George Town**, which contains the area directly occupied by the Project infrastructure, as well as communities and landholders that may be directly affected by Project construction and operation activities.

Figure 1 Site Study Area and Local Study Area for Noise and Vibration

1.3.1.3 Regional Study Area (RSA)

The Noise and Vibration RSA encompasses all lands which may provide a source of workers, goods or services for the Project as the main noise source in the existing area is the Esterly Tibbetts Highway, the RSA would include the lands connected to the Esterly Tibbetts Highway as depicted in Figure 2. The RSA has been defined conservatively to assess all likely sources of potential noise impacts to the sensitive areas surrounding the ISWMS Facility.

The maximum distance recommended for assessment is not stipulated in the United Kingdom's (UK) Institute of Environmental Management and Assessment Guidelines for Environmental Noise Impact Assessment, 2014 (IEMA). Therefore, for the purpose of this baseline noise assessment the noise at the worst-case sensitive Noise Sensitive Receptors (NSRs) within the LSA will be evaluated. The maximum noise impacts are however expected to occur at the property line and within approximately 500 m of the SSA.

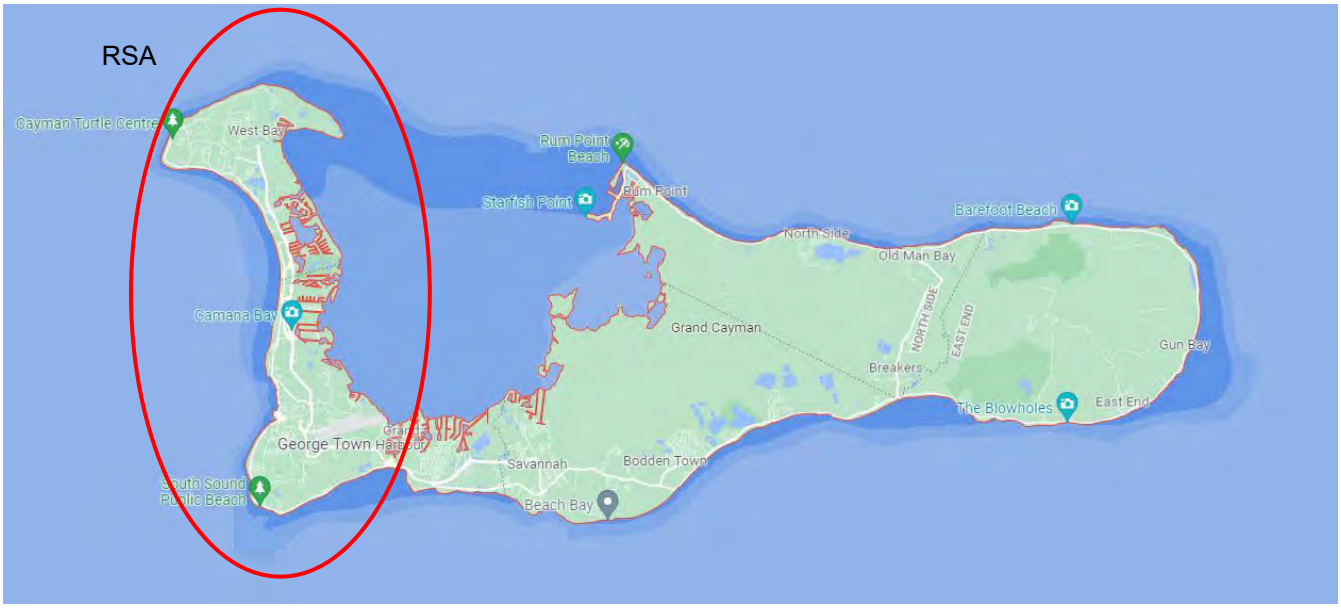

Figure 2 Regional Study Area for Noise and Vibration

1.3.2 Temporal Boundaries

There are two different types of temporal boundaries to consider. The first type are the boundaries that are associated with the temporal limits of a project. They include both large scale limits: different phases of a project (construction, operation, and closure and post-closure) and small scale limits: duration of specific project activities. Generally, the temporal boundary encompasses all project phases; however, the temporal boundary can vary depending on the Valued Components (VC) being considered. The second are the temporal characteristics associated with each VC. Temporal characteristics include both the timing and duration of critical or sensitive life stages of biological VCs (e.g., nesting and spawning periods and over-wintering). Temporal characteristics also include timing and duration of human activities (e.g., heavy tourism and recreation seasons).

For the ISWMS Project the temporal boundary limits for all VCs encompass all project phases as follows:

– **Construction (C)**: Initial Site preparation and construction (approximately 3 years)
– **Operations (O)**: Waste acceptance at the Site, ongoing landfill clearing and landfill cell construction, progressive landfill cell closure, and monitoring (approximately 25 years, depending on demand for facility services)
– **Decommissioning (D)**: removal of non-essential on-site infrastructure and closure of the facility (approximately 6 months)

Relevant temporal characteristic boundaries for Noise and Vibration include:

– Seasonal fluctuations in traffic volumes and composition
– Fluctuations in weather patterns, and their corresponding effect on Noise propagation

1.3.3 Technical Boundaries

Technical boundaries reflect the limitations in the ability to predict the effects of a project, which impose potential constraints on an assessment. An example of a technical boundary is the difficulty associated with sampling certain reclusive species, resulting in a data gap for a VC. Technical limitations are also associated with modeling and the possible margin of error in the generated data.

Technical boundaries relevant to the existing conditions assessment of Noise and Vibration include:

– Accuracy of the sound level data and traffic data used in the assessment
– Modelling accuracy
– Level of detailed design

1.3.4 Sensitive Receptor Locations – ISWMS Development

The identification of appropriate sensitive receptors is necessary to conduct the NVIA. A Noise Sensitive Receptor (NSR) is any point on the premises of a person, where sound, originating from external sources other than those that premises, is received. In general, NSRs may include: permanent or seasonal residences, nursing/retirement homes, hotels/motels, rental residences, hospitals, campgrounds, parks, schools, cemeteries or places of worship.

The objective of the NVIA is to determine the predictable worst case 1-hour equivalent sound level (1-hour Leq) at the worst case NSR(s) and to prove and ensure that the construction and operation of the ISWMS does not significantly affect the acoustic environment of the worst case NSR(s). Also, this work will ensure that should future impact assessments require equipment which that needs appropriate specifications or effective noise mitigation to meet existing sound levels, there is a reference to provide effective mitigation suggestions. The worst case NSR(s) is(are) defined as the sensitive receptor(s) with the greatest potential exposure to the ISWMS noise sources due to proximity and direct line of sight exposure.

As per the Terms of Reference (ToR), this section identifies NSRs that have the potential to be significantly affected by the main ISWMS development. The NSRs considered in the assessment include the following:

– NSR1 - Locations within the Lakeside Development (residential dwelling immediately west of the ISWMS development, on the opposite side of the Esterly Tibbetts Highway)
– NSR2 - Properties on Parkside Close (residential dwelling approximately 800 m to the northwest of the ISWMS development)
– NSR3 - Properties on Seymour Road (residential dwelling approximately 300 m to the southeast of the proposed ISWMS development)
– NSR4 - Representative of The Cayman International School (educational establishment approximately 800 m to the northeast of the ISWMS development); and Locations within the OLEA residential development approximately 800 m north of the ISWMS development
– NSR5 - Properties on Woodlake Drive/Glenwood Drive (residential dwelling approximately 300 m to the southwest of the ISWMS development)
– NSR6 – Proposed New Health City Camana Bay Medical Campus (sensitive receptor approximately 700 m to the north of the ISWMS development)

All NSR locations within 1000 m of the Facility were considered; however, the noise impact at only the worst case and most exposed NSRs are presented herein.

The location of the worst case NSRs are identified on **Figure 3 below:**

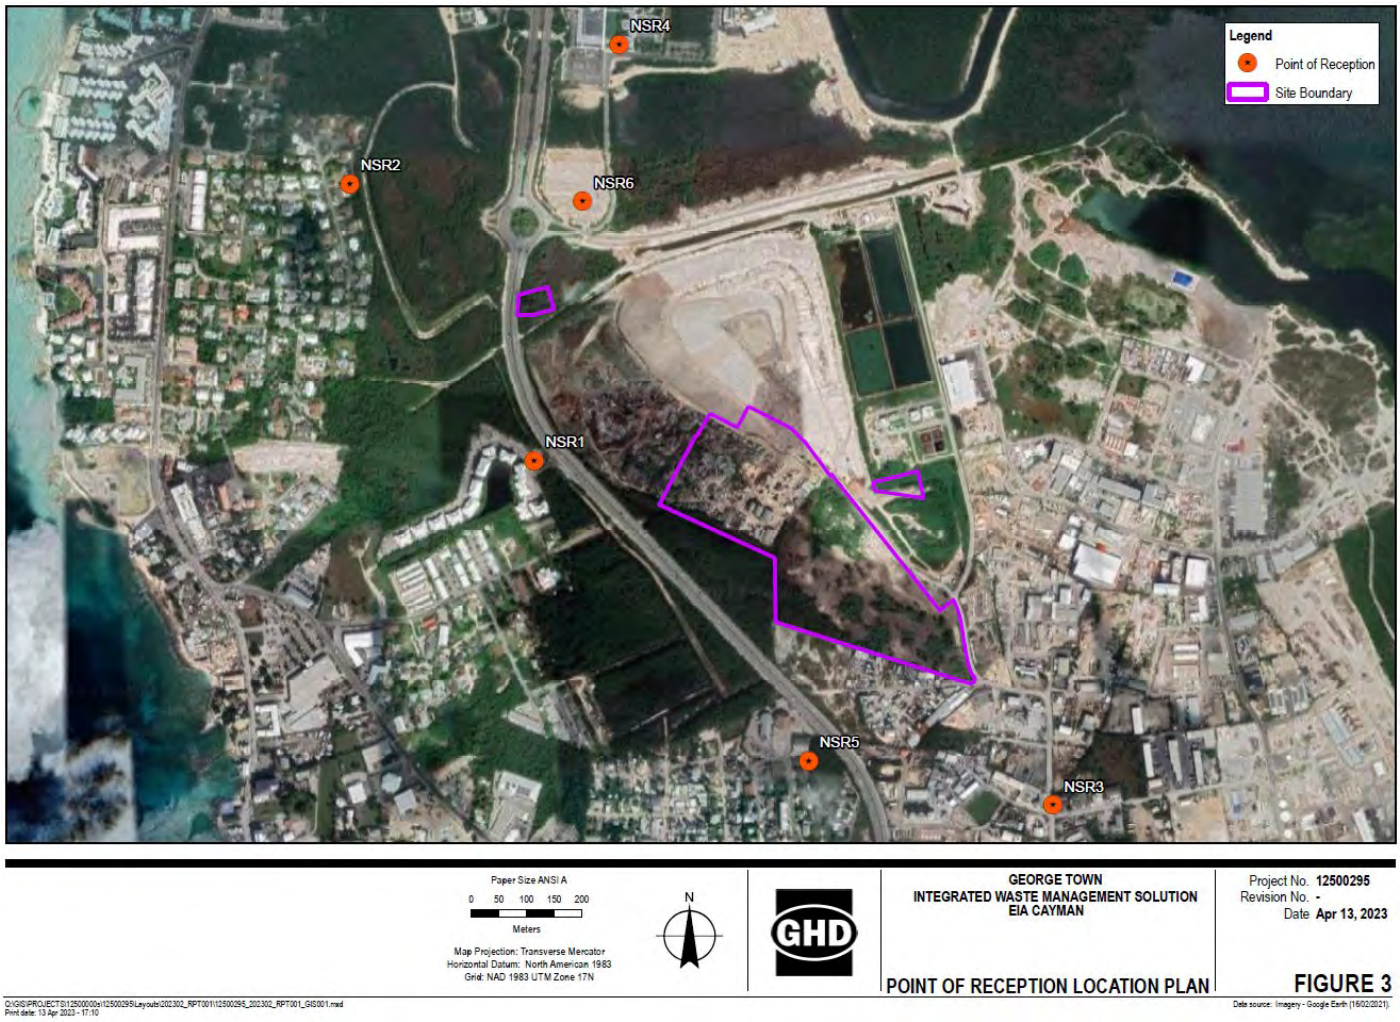

Figure 3 Point of Reception Location Plan

1.4 Existing Noise & Vibration Environment

The Cayman Islands has a total population of around 65,000 people, most of whom reside on Grand Cayman. The capital city of Grand Cayman, George Town, is located in the George Town District where the project is to be located and has a population of around 30,000 people. The population of the Cayman Island's is young compared to most developed countries, with approximately 85% of the population below the age of 55.

The economy of the Cayman Islands is mainly fuelled by the tourism and financial services sectors. Various economic impact studies put the financial services sector at approximately 50 to 60% of gross domestic product (GDP), while the tourism sector contributes between 25 to 30% of GDP – the islands having received over 2 million visitors in 2016 (mainly from the USA). Other sectors include construction, property and other business activities.

The existing ambient acoustic environment and sound characteristics around the ISWMS is mainly influenced by road traffic attributed to the local and highway roads, cruise ships, airplanes supporting the local tourism industry to the north south and west, and by existing industry to the southeast, which includes various automotive shops and ready-mix cement/concrete suppliers.

1.4.1 Existing Site and Surroundings

The land usage surrounding the proposed ISWMS site is summarised as follows:

– The existing GTLF lies immediately north and east of the proposed ISWMS site. North of this is a tidal drainage channel developed for mosquito control that connects with North Sound to the east. The Cayman International School and Camana Bay development are located approximately 0.2 miles and 0.5 miles north of the GTLF respectively.
– The land east of the GTLF is owned by Water Authority Cayman (WAC), comprising four large former wastewater treatment lagoons that are still used for sludge storage. South of the lagoons is the current wastewater treatment plant including some buildings and four smaller basins. Some 0.1 to 0.2 miles east of the landfill site is land zoned for industrial use. This is mainly undeveloped or used for open storage. The Department of Environmental Health (DEH) collections depot (comprising several trailers for staff facilities and parking for staff and collection vehicles) is located on approximately 1 acre of land to the east of the wastewater treatment lagoons within the ISWMS property. A Central Laundry Facility is also located to the east of the wastewater treatment lagoons.
– The southern boundary of the proposed ISWMS site is currently mangrove, beyond which is industrial and commercial development. This land is occupied by a variety of businesses, including a concrete batching plant and a concrete block and paver stone manufacturer.
– Esterly Tibbetts Highway (the main arterial road to West Bay) lies immediately adjacent to the fence line forming the western boundary of the proposed ISWMS site. The Lakeside residential development is located west of this road. This development comprises 12 three-storey residential apartments with car parking and leisure/landscape areas (including a small lake). The North Mound of the GTLF is visible from the easternmost lakeside buildings.
– The undeveloped parcel of the ISWMS development (Block 13D Parcel 431) is predominantly zoned Heavy Industrial (HI), which designation includes all of the activities proposed at the ISWMS Site; allowing for power generation, fuel refining and storage, solid waste disposal, recycling, quarrying and mining, mechanical and other forms of manufacture. This is consistent with the existing zoning designations and activities on the land surrounding the proposed ISWMS development.

There is one major highway and two major local roads located within the Study Area including:

1. Esterly Tibbetts Highway is a 4 lane highway that carries the majority of the traffic noise in the area around the proposed ISWMS site
2. West Bay Road is a 3-lane municipal road
3. North Sound Road is a 4-lane municipal road that becomes a 2-land road between Butterfield roundabout and Seymour Road

Vehicular road traffic generates noise that consists of mechanical noise from the engine and brakes, friction noise created from the wheel contacting the road surface, and aerodynamic wind noise from the vehicle. Traffic volume, speed, road composition, gradient and surface type will affect the overall traffic noise that can be generated. Proximity and line of sight to the road corridor are most consequential for determining the noise impact exposure for an adjacent area.

Road traffic noise is generally considered atonal broadband noise, meaning that it generates a fairly even sound distribution over the frequency spectrum with little to no predominant peaks. For any broadband noise, the audibility and potential impact from a change in the overall noise level will be a function of how much it exceeds the existing ambient background sound level or baseline noise environment. The noise generated from vehicular traffic can be defined as a line type noise source, meaning that the noise generated will reduce by approximately 3 dBA for every doubling of distance from the source.

Road traffic is scoped out and not considered to be a significant source of vibration as per ToR Section 5.7.14.

As previously completed noise monitoring describes the existing acoustic environment further north on the island it is not representative of the closest sensitive receptors to the ISWMS site and as such GHD has completed additional Baseline Noise Monitoring around the LSA.

1.5 Baseline Noise Monitoring Results

Baseline noise monitoring was necessary since noise monitoring is not routinely undertaken on the Cayman Islands, and no data is publicly available on existing levels of noise levels since the previous monitoring conducted in 2014 at other locations. The monitoring data was used in conjunction with predictive dispersion modelling using the Cadna A acoustical model to determine the potential effects of the ISWMS relative to the elevated baseline noise levels.

The objective of the baseline monitoring was to accurately measure the baseline noise levels in the area from the existing potential noise emission sources in the Study Area as detailed in the preceding Section 1.4.1.

1.5.1 Baseline Noise Monitoring Systems

Baseline sound surveys were undertaken at the agreed NSRs using 4 Larson Davis LXT (Serial Number 0006587, 0006393, 0003969, 0006585) Type 1 sound level meters as defined by BS EN 61672: Part 1: 2013 (Electroacoustics, Sound Level Meters, Specifications). All sound level meters were field calibrated before and after the measurement period by applying an acoustic calibrator that conformed to the latest versions of BS EN IEC 60942:2018 (Electroacoustics - Sound Calibrators) to the microphone to check the sensitivity of the measuring equipment. Any significant drift in calibration levels were noted. The equipment used for the noise monitoring had undergone laboratory calibration within a period not exceeding two years (one year for calibrators).

The local Cayman's airport weather station data was used to monitor weather patterns over the survey period and any periods measured under unsuitable weather conditions (precipitation and/or winds greater than 20 km/hour) were excluded from the final dataset.

The instrumentation used for the sound surveys was set up to simultaneously log, at a minimum, $L_{Aeq,T}$, $L_{A90,T}$, $L_{A10,T}$, L_{ASmin} and L_{ASmax} sound levels over continuous sampling periods for 1 hour, over a total period of 5-8 days including a weekend period. All measurements were undertaken in accordance with recognised relevant methodologies such as BS 4142:2014. The baseline sound survey results were then defined against, BS4142:2014 in terms of background sound levels (defined as the L_{eq}, $L_{A90,\,T}$ parameter) in compliance with the requirements of the EAB scoping opinion, per Section 5.7.17 in the ToR. Section 5 of the scoping opinion states that "noise levels from the proposed activities should be calculated and assessed against baseline conditions and relevant standards, taking into account cumulative effects of adjacent activities and land uses".

The noise descriptors are described as the following:

- $L_{Aeq,\,T}$ – This is the A-weighted sound level of a steady sound carrying the same total energy in the time period T as the observed fluctuating sound. The time period T is given in hours. Leq without a specific time period means Leq.
- $L_{A90,T}$ – This is sound the level that is exceeded for 90% of the time and is often used to quantify the background noise levels in assessments of noise pollution and nuisance noise from industrial sources.
- $L_{A10,T}$ – This is sound the level that is exceeded for 10% of the time and takes account of any annoying peaks in noise.
- L_{ASmin} and L_{ASmax} – the minimum and maximum L_{Aeq} within a period of time.

The baseline noise monitoring program followed these standards. Unattended baseline monitoring was selected due to the variability of the sound levels in an urban environment and since the ISWMS will run year-round, a more long-term evaluation is required to best evaluate the existing conditions. The month of October was selected due to favourable weather and because local schools would be in session depicting typical traffic patterns for the area.

1.5.2 Duration of Baseline Noise Monitoring

Seasonality on the Cayman Islands consists of a wet and a dry season. The dry season usually begins in early November and lasts until April. The monitoring took place beginning in October 2021 which measured noise emissions

occurring just prior to the start of the rainy season but after the summer school break so regular traffic is observed and documented with regards to ambient noise in the area.

Baseline monitoring was completed for 8 days at NSRs 1, 3, and 4. The Baseline monitoring at NSR2 however was only completed over 5 days due to difficulty obtaining permissions and access to that location. This is still within the minimum 5 day required total period for determining background sound levels. All baseline monitoring included both weekday and weekend days for evaluation. Monitoring at NSR1 is considered representative of NSR5 due to the same line of sight, exposure and separation distance (~50m) to Esterly Tibbetts Highway. Monitoring at NSR4 is considered representative of NSR6 due to similar proximity to Esterly Tibbetts Highway.

Photographs of the monitoring locations are included in Appendix D.

1.5.3 Baseline Noise Monitoring Results

Continuous one-hour L_{Aeq}s were taken with the detector in slow response over the course of the measuring period when meteorological conditions consisted of low winds (less than 15 kilometers per hour [km/hr]), and minimal precipitation or were otherwise excluded due to weather. The baseline noise monitoring was conducted from October 19, 2021 to October 27, 2021 with all statistical sound level measurements including $L_{Aeq,T}$, $L_{A90,T}$, $L_{A10,T}$, L_{ASmin} and L_{ASmax} over continuous hourly sampling periods for each monitoring location in addition to providing the average for the weekday periods of monitoring program as summarized in Tables D.1-D.4 of Appendix D.

The daytime, evening, and nighttime statistical sound levels are summarized for each monitoring location are shown below:

Table 1 Baseline Noise Monitoring Week Summary

NSR	Average Daytime (dBA) LAeq, 11 hour	Average Evening (dBA) LAeq, 5 hour	Average Night Time Level (dBA) LAeq, 8 hour	Daytime Range (dBA) LA90, 11 hour	Evening Range (dBA) LA90, 5 hour	Night time Range (dBA) LA90, 8 hour
NSR1 – Lakeside Development (7.5 metres above grade [m AG])	63	58	58	51 - 59	49 - 54	45 - 47
NSR2 – Residence on Parkside Cl. (4 m AG)	56	48	44	43 - 46	40 - 43	36 -40
NSR3 – Residence on Seymour Rd. (1.5 m AG)	65	57	57	53 - 57	52 - 54	49 - 53
NSR4 – Cayman International School (4.5 m AG)	61	54	51	43 - 52	42 - 45	38 - 41
NSR5 – Residence on Woodlake Drive (1.5 m AG)	63	58	58	51 - 59	49 - 54	45 – 47
NSR6 – Proposed New Health City Camana Bay Medical Campus (7.5 m AG)	61	54	51	43 - 52	42 - 45	38 - 41

Note that NSR1 baseline data is used to represent NSR5 and NSR4 baseline data is used to represent NSR6 due to similar proximity to Esterly Tibbetts Highway.

The average L_{90} hour for each monitoring period is typically used for comparison to the proposed operational impacts of the ISWMS, as this is the period in which the ambient environment is at its lowest and is therefore conservative criteria to evaluate potential noise impacts relative to the ambient.

2. Applicable Standards and Guidelines

Cayman Islands is an overseas British Territory. Noise and Vibration guidance regarding baseline monitoring will therefore be referenced from the current EU Directives as noted in Table 5.33 of the ToR:

– UK's Institute of Environmental Management and Assessment Guidelines for Environmental Noise Impact Assessment, 2014 (IEMA)

As stated in the ToR, emissions in the Cayman Islands are guided by the UK's Institute of Environmental Management and Assessment Guidelines for Environmental Noise Impact Assessment, 2014 (IEMA) which presents guidelines on how the assessment of noise effects should be presented within the Environmental Impact Assessment (EIA) process. The IEMA guidelines cover aspects such as; scoping, baseline, prediction and example definitions of significance criteria.

The applicable guidance is summarized as follows:

– British Standard 5228-1:2009+A1:2014 Code of Practice for noise and vibration control on construction and open sites – Part 1: Noise (BS5228-1)
– British Standard 5228-2:2009+A1:2014 Code of Practice for noise and vibration control on construction and open sites – Part 2: Vibration (BS5228-2)
– UK's Highways Agency Design Manual for Roads and Bridges, 2011 (DMRB)
– British Standard 4142+A1:2019: Methods for rating and assessing industrial and commercial sound (BS4142)
– British Standard 8233:2014 Guidance on sound Insulation and noise reduction for buildings (BS8233)
– British Standard 6472-1:2008 Guide to evaluation of human exposure to vibration in buildings. Part 1: Vibration sources other than blasting (BS6472)
– UK's Department of Transport Calculation of Road Traffic Noise, 1988 (CRTN)
– Acoustics – Attenuation of sound during propagation outdoors: Part 2 General Method of Calculation, 1996 (ISO 9613-2)
– UK's Institute of Environmental Management and Assessment Guidelines for Environmental Noise Impact Assessment, 2014 (IEMA)
– Potential noise impacts at educational facilities – Acoustic design of schools: performance standards: Building bulletin 93, 2015 (BB93)
– Cayman Islands Government Department of Environmental Health – Guidelines for Development Control (2009 Revision) - Section 4.4 - Noise Pollution Control (https://www.gov.ky/deh/publications.html)

The potential noise effects associated with the ISWMS have been assessed in accordance with the guidance detailed in the following sections to determine whether statutory objectives are exceeded or whether undesirable/desirable consequences may arise for the receiving environment. Where potential adverse impacts are identified, appropriate mitigation measures are proposed to avoid, reduce or compensate for the adverse effects. The significance of an environmental impact will be determined not only by the magnitude of the impact but also by the sensitivity of the receptor. The significance of construction noise and vibration, and operational noise, is detailed below, respectively, as well as the determination of the sensitivity of the receptor.

2.1 Assessment Criteria for Operational Noise Effects

For each NSR the ISWMS operational noise assessment methodology, as described in BS 4142:2014, comprises:

– Ascertaining a representative $L_{A90,\,T}$ background sound level at the NSR from the results of baseline sound survey.
– Calculating or modelling the free-field $L_{Aeq,Tr}$ specific sound level (due to each item of plant) at said NSR and applying a character correction (for tonality, intermittency and impulsivity, if appropriate) to obtain the free-field

$L_{Ar, Tr}$ rating level – for the identification of tonality, reference should be made to 1/3rd octave data if such data is available.

– Performing a decibel addition to obtain the cumulative effect (where appropriate) of all relevant $L_{Ar, Tr}$ rating levels on the NSR.
– Arithmetically subtracting the $L_{A90, T}$ background level from the cumulative $L_{Ar, Tr}$ rating level to obtain the excess of rating level over background level for the assessment.
– The assessment criteria for EIA magnitude of change has been derived from the assessment criteria described in section 11 of BS 4142: 2014 and is given in Table 2.

Table 2 EIA Magnitude of Change Assessment Criteria

EIA Magnitude of Change	Excess of Rating over Background Sound Level, dB	Typical BS 4142:2014 Assessment Outcome
Very High	> 12	A difference of around +10 dB or more is likely to be an indication of a significant adverse impact depending on context
High	8 – 12	A difference of around +10 dB or more is likely to be an indication of a significant adverse impact depending on context
Medium	3 – 7	A difference of around +5 dB is likely to be an indication of an adverse impact depending on context
Low	0 – 2	Less than an indication of adverse impact, depending on context
Very Low	< 0	Where the rating level does not exceed the background sound level, this is an indication of the specific sound source having a low impact, depending on context.

For the purposes of BS4142:2014, adverse impacts include, but are not limited to, annoyance and sleep disturbance. However, it should be noted that not all adverse impacts will lead to complaints and not every complaint is proof of an adverse impact.

Table 3 Sensitivity of Receptor

Sensitivity	Receptor Type
High	**Receptor/resource has little ability to absorb change without fundamentally altering its present character or is of international or national importance. For example, hospitals, residential care homes, and internationally and nationally designated nature conservation sites which are also known to contain noise sensitive species (i.e., noise may change breeding habits or threaten species in some other way).**
Medium	**Receptors/resource has moderate capacity to absorb change without significantly altering its present character. For example, residential dwellings, offices, schools, and play areas. Locally designated nature conservation sites which are also known to contain noise sensitive species (i.e., noise may change breeding habits or threaten species in some other way).**
Low	Receptor/resource is tolerant of change without detriment to its character or is of low or local importance. For example, industrial estates.
Negligible	Receptor/ resource is not sensitive to noise.

The NSRs identified have been assessed to have medium sensitivity as noise & vibration assessments primarily apply to residential receptors in the ISWMS development area, with the exception of NSR6 and NSR4, which are assessed high sensitivity due to being a hospital and a school, respectively.

The significance of an environmental impact for on-site operational noise is determined by the interaction of magnitude and sensitivity. The Significance Evaluation Matrix used in this assessment is shown in Table 4:

Table 4 Significance Evaluation Matrix

		Magnitude of Change				
		Very High	**High**	**Medium**	**Low**	**Very Low**
Sensitivity	**Very High**	Major (Significant)	Major (Significant)	Major (Significant)	Major (Significant)	Moderate (Possibly significant)
	High	**Major (Significant)**	**Major (Significant)**	**Major (Significant)**	**Moderate (Possibly significant)**	**Minor (Not significant)**
	Medium	**Major (Significant)**	**Major (Significant)**	**Moderate (Possibly significant)**	**Minor (Not significant)**	**Negligible (Not significant)**
	Low	Major (Significant)	Moderate (Possibly significant)	Minor (Not significant)	Negligible (Not significant)	Negligible (Not significant)
	Very Low	Moderate (Possibly significant)	Minor (Not significant)	Negligible (Not significant)	Negligible (Not significant)	Negligible (Not significant)

Within the matrix that is used in most significance evaluation exercises, reference is made to:

– Major effects, which will always be determined as being significant.
– Moderate effects that are likely to be significant, although there may be circumstances where such effects are considered ‘not significant' based on specific scenarios and professional judgement.
– Minor or negligible effects, which will always be determined as ‘not significant'.

Additionally, Moderate impacts might be noticeable and intrusive but may cause only a small change in behaviour, while significant impacts might be noticeable and disruptive and might cause a material change in behaviour or attitude.

2.2 Assessment of Operational Traffic Noise Effects

Predictions of the relative increase in traffic noise levels will be undertaken where data indicates that there will be an increase of 25% or decrease of 20% in existing traffic levels or if there is an increase of more than 1 dBA due to heavy goods vehicle (HGV) traffic increases on the main route(s) to the development.

The Operational Traffic Roads includes the following roads: Seymour Road, North Sound Road, Thomas Russel Avenue, Elgin Avenue, Goring Avenue, Harbour Drive and Esterly Tibbets Highway. The BNL was predicted using noise emission rates in accordance with CRTN calculations using total flows, mean speed and %HGVs.

18-hour (06:00 – 24:00) traffic counts from 2017 and 2019 for all roadways were obtained from the National Roads Authority (Cayman Islands) and manual traffic counts for Seymour Road were completed in December 2022 and January 2023. Traffic data collected from automatic traffic counters between December 2 and 16, 2022 as part of a

Traffic Study by APEC Consulting Engineers Limited was also used. These counts were used to determine the minimum hourly count during the day, evening, and nighttime periods.

Table 5 Operational Roads Traffic Parameters

Road Segment	Daytime Vehicle Count (06:00 – 00:00)	Night-time Vehicle Count (00:00 – 06:00)	Speed Limit (miles/hour)	%HGVs
Seymour	4405	277	25	9%
N Sound Rd. (West of Seymour Rd.)	10125	637	35	15%
N Sound Rd. (East of Seymour Rd.)	8628	543	35	15%
Thomas Russel Ave.	34102	899	35	11%
Elgin Ave.	19629	526	25	7%
Goring Ave.	19629	526	25	7%
Harbour Dr.	23107	686	25	15%
Esterly Tibbetts Highway	31185	816	40	15%

The above road traffic data was used to calculate the Haul Road noise levels. Note that North Sound Road east of Seymour Road is not part of the Haul Route, but is included to account for traffic coming from that direction.

The rounded road traffic noise modeling results are summarized as follows:

Table 6 Existing Operational Traffic $L_{A10, 18hr}$ Noise Impact Levels

NSR	Existing 18 hr Daytime Operational Road Traffic $L_{A10, 18hr}$ (dBA)	Existing 6 hr Night-time Operational Road Traffic $L_{A10, 6hr}$ (dBA)
Seymour	65	58
N Sound Rd. (West of Seymour Rd.)	71	64
N Sound Rd. (East of Seymour Rd.)	71	63
Thomas Russel Ave.	76	65
Elgin Ave.	71	61
Goring Ave.	71	61
Harbour Dr.	74	64
Esterly Tibbetts Highway	77	66

Any increase will be assessed in terms of the criteria given in DMRB based on the magnitude of change for the long-term as the operation traffic will be a long-term effect and is defined in Table 7 below:

Table 7 Magnitude of Change of Operational Traffic Noise Effects –Long Term

Magnitude	Long Term Noise Change (dBA $L_{A10,18hr}$)
Major	Greater than or equal to 10.0
Moderate	5.0 to 9.9
Minor	3.0 to 4.9
Negligible	Less than 3.0

Once the magnitude of change is determined, the Significance Evaluation Matrix (Table 4) will be consulted to determine the significance of the impact. It is expected that operational traffic noise change will be considered long term noise change.

2.3 Assessment Criteria for Construction Noise Effects

The activities associated with the construction phase of the ISWMS have the potential to generate noise and create an impact on the surrounding area. The potential noise impact during the construction phase has been assessed against the BS5228-1 ABC method. The magnitude of any impacts has been established, and the significance of the construction noise impact has been determined.

In addition to the construction activities, construction vehicle movements to and from the site have the potential to generate noise at existing sensitive receptors, in the immediate vicinity of the local road network. This potential noise impact has been considered against the existing baseline noise levels and vehicle movements within the local area.

The British and International standard Construction & Operational Road Traffic Noise by the UK's Highways Agency Design Manual for Roads and Bridges (DMRB) is widely used as reference for construction noise impact assessments. The DMRB guidance scope of construction noise by first understanding if construction noise generated by the project has the potential to adversely affect any sensitive receptors. Second, the DMRB asks if the scale of the development or receptors warrant there a reasonable stakeholder expectation to undertake a noise assessment. In this case the answer to both would be yes, therefore a noise assessment must be undertaken.

The DMRB assesses areas based on the baseline noise of an area. The noise assessment will be based on GHD's baseline noise data collected from October 19, 2021 to October 27, 2021, since data from other sources was not sufficient to enable production of a proportionate construction noise assessment.

The DMRB determines significance based on the lowest observed adverse effect level (LOAEL), and the significant observed adverse effect level (SOAEL) as follows:

Table 8 Magnitude of Impact and Construction Noise Descriptions

Magnitude of Impact	Construction Noise Level
Major	Above or equal to SOAEL +5 dB
Moderate	Above or equal to SOAEL and below SOAEL +5 dB
Minor	Above or equal to LOAEL and below SOAEL
Negligible	Below LOAEL

The DMRB establishes that the LOAEL is the ambient noise level, and the SOAEL is determined by the BS5228-1 threshold value (see Table 9 on next page).

Construction noise will be predicted using the methodology indicated in BS5228-1:2009+A1:2014 for all the main phases of the construction works, including any cumulative noise associated with simultaneous operation of construction activities within different phases.

The results from these predictions will be assessed against the ABC methodology within Annex E of this Standard and will be based on the prevailing ambient noise levels measured as part of the study.

Table 9 The ABC Method of Determining the Threshold Noise Levels of Potential Significant Effect at Dwellings

Assessment Category and Threshold Value Period	Threshold Value, in decibels (dB), $L_{aeq,T}$		
	Category A[A]	Category B [B]	Category C [C]
Night-time (23:00 – 07:00)	45	50	55
Evenings and weekends	55	60	65
Daytime (07:00 – 19:00) and Saturdays (07:00 – 13:00)[D]	65	70	75
[A] Category A: threshold values to use when ambient noise levels (when rounded to the nearest 5 dB) are less than these values.			

Assessment Category and Threshold Value Period	Threshold Value, in decibels (dB), $L_{aeq,T}$		
	Category A[A]	Category B [B]	Category C [C]
[B] Category B: threshold values to use when ambient noise levels (when rounded to the nearest 5 dB) are the same as category A values. [C] Category C: threshold values to use when ambient noise levels (when rounded to the nearest 5 dB) are higher than Category A values. [D] 19:00 – 23:00 weekdays, 13:00 – 23:00 Saturdays and 07:00 – 23:00 Sundays.			

A potential significant effect is indicated if the $L_{Aeq,T}$ noise level arising from the site exceeds the threshold level for the category appropriate to the ambient noise level. If the ambient noise level exceeds Category C threshold values given in the table (i.e. the ambient noise level is higher than the above values), then a potential significant effect is indicated if the total $L_{Aeq,T}$ noise level for the period increases by more than 3 dB due to site noise. This table applies to residential receptors only.

Chapter 4 of the Environmental Statement specifies that all construction work and ancillary operations that are audible at sensitive receptors shall be carried out between the hours of 8 am – 6 pm. Thus, the daytime values will be determined using this method.

Table 10 Threshold Limits for Noise Sensitive Receptors

Noise Sensitive Receptor	Daytime Ambient Leq (dBA) (07:00 – 19:00)	Rounded to Nearest 5 dBA	BS-5228 Category	Daytime Threshold (dBA)
NSR1 – Lakeside Development (7.5 metres above grade [m AG])	63	65	B	**70**
NSR2 – Residence on Parkside Cl. (4 m AG)	56	55	A	**65**
NSR3 – Residence on Seymour Rd. (1.5 m AG)	66	65	B	**70**
NSR4 – Cayman International School (4.5 m AG)	60	60	A	**65**
NSR5 – Residence on Woodlake Drive (1.5 m AG)	63	65	B	**70**
NSR6 - Proposed New Health City Camana Bay Medical Campus (7.5 m AG)	60	60	A	**65**

In order to rate the magnitude of potential significant effects, the modelled results are then considered against the criteria in Table 11, which specifies a magnitude of change based on the threshold values and temporal considerations.

Table 11 Construction Noise EIA Magnitude of Change Criteria

EIA Magnitude of Change	Criteria
Very High	Exceeds BS 5228 threshold values for one month or more by 10 dB or more or any of the trigger levels for more than nine days in a 15-day period by 10 dB or more.
High	Exceeds BS 5228 threshold values for one month or more by less than 10dB or any of the trigger levels for more than 9 days in a 15-day period by less than 10 dB.
Medium	Exceeds BS 5228 threshold values or trigger levels by less than temporal criteria of significance.
Low	Is within < 10 dB below BS 5228 threshold values or trigger levels.
Very Low	Is more than 10 dB below BS 5228 threshold values or trigger levels.

Once the magnitude of change is determined, the Significance Evaluation Matrix (Table 4) will be consulted to determine the significance of the impact.

2.4 Assessment Criteria for Construction Road Traffic Noise

GHD generated the Basic Noise Level (BNL) at the NSR locations based on traffic counts to evaluate the existing background noise due to road traffic on the Construction Haul Road that runs from the Facility to the Ports as depicted below:

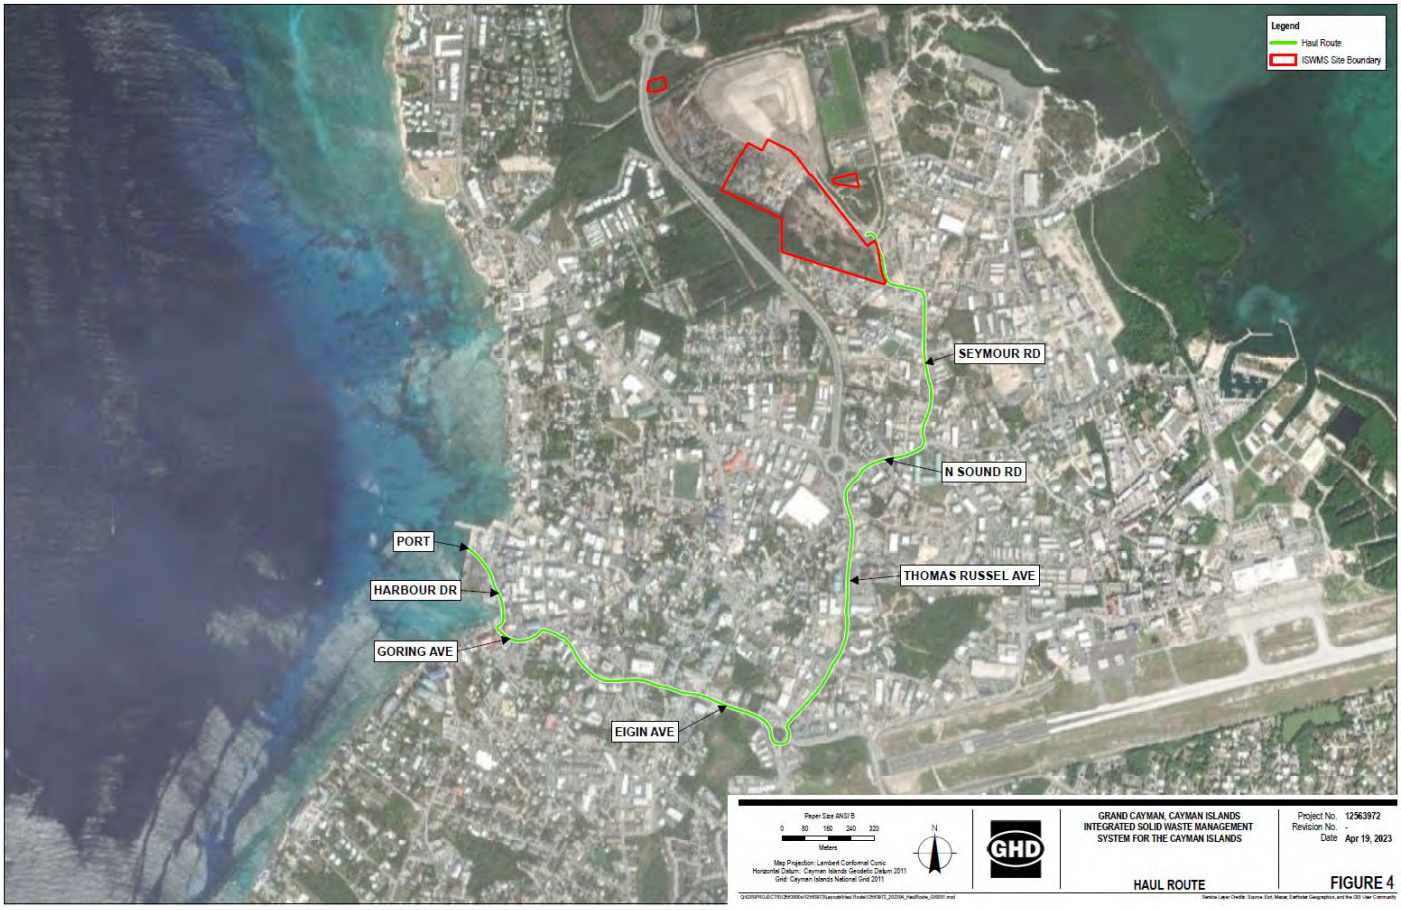

Figure 4 Construction Haul Road

The Haul Road includes the following roads: Seymour Road, North Sound Road, Thomas Russel Avenue, Elgin Avenue, Goring Avenue and Harbour Drive. The BNL was predicted using noise emission rates in accordance with CRTN calculations using total flows, mean speed and %HGVs and can be found in Table 6 in Section 2.2 above.

The limits in Table 6 will be used in the significance assessment made against the short-term impact criteria from DMRB. Table 12 sets out the relevant impact assessment criteria, which will then be compared against Table 4 to determine the significance of the impact.

Table 12 Construction Traffic Short-Term Impact Assessment Criteria

EIA Magnitude of Change	Noise Change $L_{A10,18hr}$ (dB) Criteria	DMRB Short-Term Magnitude of Impact
Very High	N/A	N/A
High	5+	Major
Medium	3 – 4.9	Moderate

EIA Magnitude of Change	Noise Change $L_{A10,18hr}$ (dB) Criteria	DMRB Short-Term Magnitude of Impact
Low	1 – 2.9	Minor
Very Low	0.1 – 0.9	Negligible
No Change	0	No Change

2.5 Assessment Criteria for Construction Vibration

It is expected that during the construction phase there may be some items of plant that could give rise to significant levels of vibration due to activities such as piling if they occur close enough to the sensitive receptors. The assessment criteria given in Table 2.5 (below) has been adopted from Table B.1 of BS5228-2:2009+A1:2014 and should be used to assess the EIA magnitude of change.

Construction Vibration Short-Term Impact Assessment Criteria

EIA Magnitude of Change	Peak Particle Velocity, PPV (mm/s) Criteria
Very High	> 10 mm/s
High	Between 5 mm/s and 10 mm/s
Medium	Between 1 mm/s and 5 mm/s
Low	Between 0.3 mm/s and 1 mm/s
Very Low	< 0.3 mm/s

Per the ToR for this project an evaluation of vibration impacts was excluded due to the ISWMS site operations not having any significant vibratory potential. Additionally, GHD has screened out potential construction vibratory impacts from the worst-case construction equipment including the use of heavy vibratory equipment sources such as impact hammer pile driving. The assessment of vibration effects was made by using the empirical formulas in Table E.1 of BS5228-2:2009+A1:2014 and by referring to the historic data (or manufacturer's data, where available) within the same standard.

GHD evaluated all surrounding sensitive receptors and determined that all sensitive structures/locations are greater than 258 m away from the closest proposed construction activities. GHD determined that the worst-case construction vibration activities such as the use of heavy vibratory equipment sources (impact hammer pile driving) have a maximum zone of influence of 30 meters. Based on a significant buffer distance of 228 m from the zone of influence GHD has deemed construction vibration insignificant for all receptors noting an EIA magnitude of change of "very low" as the vibration impacts would be <0.3mm/s PPV below the Lowest Observed Adverse Effect Level (LOAEL). Based on this evaluation and the significant buffer distance further vibration assessment is not warranted for this EIA process.

3. Assessment Methodology

Available secondary sources of information were collected and reviewed to characterize the Noise existing conditions within the study areas. The following sources of secondary information were collected and reviewed:

– Review of historic complaints
– Review of current zoning plans, definitions and land use designations
– Aerial photographic mapping and field reconnaissance to confirm off-Site receptors
– ISWMS design and operation data and associated topography
– Cruise Berthing Terminal for Cayman Islands - Final EIA Terms of Reference (Mott MacDonald, 2013)

– Grand Cayman Waste Management Facility Draft Environmental Statement (Carddno ENTRIX, 2013)
– Integrated Solid Waste Management System for the Cayman Islands: Environmental Impact Assessment- Terms of Reference. (Wood, 2021)
– Directive for Environmental Impact Assessments Section 43, National Conservation Law (Extraordinary No. 50/2016)
– Proposed Cruise Berthing Facility, Grand Cayman. Environmental and Engineering Consultancy Services: Environmental Statement – Draft. (Baird, 2015)
– Environmental Impact Assessment Scoping Opinion (Environmental Assessment Board (EAB), (EAB, 2017)

The likely significant noise effects that have been taken forward for assessment are summarised in Table 13:

Table 13 Likely Significant Noise Effects

Activity	Effect	Receptor
Site Construction	Emission of noise causing effects on health and quality of life at sensitive receptors	Residential properties, schools, commercial sites
Site Operations	Emission of noise causing effects on health and quality of life at sensitive receptors	Residential properties, schools, commercial sites

In summary, the following general noise assessment methodology was followed:

– The assessment considers the baseline noise levels at existing sensitive receptors and the potential effect of the noise from activities associated with the ISWMS at each receptor.
– Unattended background noise monitoring was undertaken during the daytime and night-time periods at the locations which are representative of the existing sensitive receptors surrounding the site.
– The potential noise impact during the construction phase has been assessed against the BS5228-1 ABC method. The magnitude of any impacts will be established, and the significance of the construction noise impact will be determined.
– The potential noise levels from the ISWMS will be predicted using noise data provided by the Client. These noise emission levels will be used in noise modelling software CadnaA 2023 to create a noise model of the ISWMS and the surrounding area.
– The calculated noise levels will be compared against measured baseline noise levels and guidance contained within British Standard 4142 + A1:2019: Methods for rating and assessing industrial and commercial sound (BS4142).
– To reduce the potential impact of operational noise from the development on existing receptors, mitigation measures will be recommended as required.

3.1 Noise Modelling and Prediction Methodology

Through this assessment, the Project team has quantified the proposed noise levels in the Study Areas by using the appropriate CadnaA Acoustical Modelling Software (CadnaA) 2023 to model the potential impacts of the significant noise sources based on assumptions of typical equipment numbers and locations. CadnaA uses geographical information to generate a model of the study area to generate noise contours. The noise model includes all proposed site buildings and significant sources of noise associated with the operations of the facility. CadnaA calculates sound level emissions based on the ISO 9613-2 standard "Acoustics – Attenuation of Sound during Propagation Outdoors".

The worst-case cumulative site-wide sound levels estimated at the receptor(s) included attenuation effects due to geometric divergence, atmospheric attenuation, barriers/berms, ground absorption and directivity, as applicable significant noise sources at off-site buildings were input into the model as intervening structures.

CadnaA modelling assumptions applied include the following:

– Noise Sources | All sources were modelled using the 1/1 octave band data from manufacturer's sound level data or reference materials.
– Noise Source Elevation | The heights of the noise sources were modelled at the tallest point to represent the worst-case line of sight and emission of noise.
– Ground Absorption | The model included water (G=0), soft/porous ground (G=1), and gravel/hard ground (G=0.25).
– Receptor elevation | NSR heights were modelled appropriately to represent the worst-case elevation based on one or two-storey residences at the worst-case compass directions from the Site.
– Time-weighted Adjustment | Time-weighted adjustments for sources that do not operate continuously were utilized.
– Tonality | A +5 dBA adjustment was applied for tonal sources, if applicable.
– Building Surfaces | The buildings are modelled as reflective surfaces.
– Foliage | Foliage attenuation was not considered in our analysis as a conservative assumption.

Table14 outlines the acoustic modelling parameters used:

Table 14 Acoustic Modelling Parameters

Item	Model Parameters	Model Setting
1	Temperature	20°C
2	Relative humidity	70%
3	Wind speed	Downwind condition; wind speed of 3 m/s
4	Max. Search Radius (m)	2000 m
5	Noise propagation model	CadnaA (DataKustik 2023)
6	Standard	ISO 9613
7	Terrain parameters	Site Specific topography was used
8	Reflection parameters	1 order of reflection

In order to predict the future worst-case noise impacts from the Project activities, representative octave band noise data was used, measured from construction/processing equipment similar to what is noted to be required for the Project. This data was obtained from Annex C of the British Standard BS5228:2009+A1:2014 Code of Practice for noise and vibration control on construction and open sites – Part 1: Noise. The United States Department of Transportation, Federal Highway Administration (FHWA) document FHWA Roadway Construction Noise Model User's Guide, 2006 as well as GHD's own reference spectra were used as supplemental documents to obtain sound level data for equipment not listed by BS5228.

Site-specific topography was acquired from a photogrammetry survey completed by DECCO Consortium (DC) dated July 16, 2021 and various publicly available LIDAR and geospatial databases including USGS, CGIAR, NASA and NGA.

A 3D noise model was created in CadnaA with each significant noise source, vehicle path and operations building included. Noise prediction calculations have been undertaken to predict the noise levels likely to be generated by typical operational activities associated with the proposed ISWMS and the resultant noise levels at existing sensitive receptor locations.

The calculated noise levels have then been compared against measured background sound levels following the guidance in BS4142, and potential impacts evaluated. The magnitude of any impacts has been established, and the significance of the operational noise impact has been determined. In addition to the operational noise from the ISWMS, vehicle movements to and from the ISWMS Development have the potential to generate additional noise at

existing sensitive receptors, in the immediate vicinity of the local road network. This potential noise impact has been considered against existing baseline noise levels and existing vehicle movements within the local area.

The worst-case assessment of all road traffic noise was predicted using noise emission rates from road traffic in accordance with CRTN calculations.

Vibration is not considered to be a significant effect during the operational phase of the proposed development and has been scoped out of the assessment. Mitigation measures would be incorporated within the design of the facility in order to reduce or remove any vibration that would result from operation of the site.

The prediction calculations have utilized noise measurement information provided by the Client. The potential sources of noise associated with the proposed ISWMS are detailed in Section 4 of this assessment. The calculations have been carried out in accordance with the prediction methodologies set out in BS5228-1 and BS4142. To reduce the potential impact of operational noise from the ISWMS on existing receptors, mitigation measures will be implemented into the design of the ISWMS. These measures are discussed in Section 4.1.

4. Noise Impact Assessment

This Section reports the likely effects of the Proposed Development in terms of noise impacts in the context of the Site and surrounding area, and whether these would be deemed to be significant. In particular it considers the likely effects of noise from the Proposed Development and its impact on nearby receptors.

4.1 Design Assumptions and Mitigation Summary

The following section details assumptions in the current design and operations of the ISWMS with the associated noise mitigation that was incorporated into the acoustical evaluation for future reference during detailed design of the Facility.

4.1.1 Energy Recovery Facility (ERF)

The ERF will be in the form of a conventional energy recovery facility, which will sustainably manage non-hazardous and non-recyclable residual waste. The ERF will operate 24 hours per day, 7 days per week, 365 days per year. Non-hazardous commercial, construction and industrial waste will be received on site at the ERF between the hours of 07:00 to 18:00 Monday to Friday and 07:00-12:00 on a Saturday.

The waste reception area has been designed to allow ease of access and the most efficient delivery of waste to the facility, which will see waste being delivered via a range of vehicles, including bulk articulated vehicles, refuse collection vehicles, compactors and skip tippers.

Fast acting roller shutter doors will allow multiple delivery vehicles to enter the tipping hall simultaneously. On entering the reception hall vehicles will discharge their payload directly into the waste bunker. Front end loaders will be employed to manage the incoming waste where it cannot be discharged directly into the waste bunker, for example where waste must be quarantined within the waste reception hall.

The fast-acting automatic doors for the tipping hall and roller shutter doors and are understood to provide 10 dB and 18 dB noise attenuation respectively. GHD has conservatively assumed that 50% of the bay doors will be open at any one time and have modelled the breakout emissions from the open doors only.

The design layout and design measures have been considered to minimize the noise impacts associated with the design of the Facility.

Most of the ‘noisy' plant items at the Facility will be installed within the main building and equipped with appropriate noise insulation, if necessary. The air-cooled condensers will be designed to reduce noise and tonal components. If steam bursting discs or pressure relief valves release externally to the building, they will be fitted with appropriate

silencers. Doors to the building will be kept closed when not in use in order to prevent noise emissions, with doors to the tipping hall and turbine acoustically rated to appropriate levels.

Vehicle movements at night will be limited where possible and vehicles will be fitted with non-tonal reversing alarms. A one-way system will be in place for HGVs and waste delivery vehicles so they will only reverse once inside the tipping hall. Regular maintenance of plant items will be undertaken in accordance with preventative maintenance procedures.

Any mobile plant to be used on-site will be operated and maintained in accordance with the manufacturer's instructions, whilst complying with the latest standards including those on noise emissions.

There are many aspects associated with noise mitigation which need to be considered, including the following:

– General approach and experience of the Technology Provider
– Tonal noise
– Low frequency noise
– Noise associated with operational emergency steam relief and commissioning steam venting
– General design measures

Plant areas which contain higher than ambient noise sources (e.g., the Turbine Hall, Boiler and Flue Gas Treatment rooms) contain a significant number of individual items of process plant. Trying to abate noise from all of them independently is impracticable, and creates problems with temperature control, access for online operational maintenance, routine observation and ventilation requirements which further limits attenuation at source. Therefore, suitable and efficient layouts and design solutions will be employed, including acoustically designed plant rooms, which will limit noise emissions to the acceptable levels needed comply with all relevant regulations.

The following sub sections present details on noise mitigation measures proposed for the ERF Facility.

4.1.1.1 Principal Noise Sources with Specific Noise Mitigation Measures Incorporated into the Design

The principal operational noise sources from the ERF Facility that have noise mitigation included in the design are as follows:

– ERF Building Shell and Sidewall Air Intakes/Exhausts
– Main stack outlet
– ID Fan (enclosed)
– Turbine hall
– ERF waste reception area or ‘tipping hall'

The principal noise sources and mitigation measures assumed in the noise modelling for each of these areas are set out in the subsequent sections. As the design specification for internal and external plant has yet to be finalised, the noise assessment presented in this NVIA utilises operational noise impact information from a similar sized energy recovery facility in which GHD is familiar with. For the purposes of the assessment, it has been assumed that the majority of the identified sound sources would operate continuously and simultaneously, during both the daytime and night-time periods. However, at night it has been assumed that there would be no reception of waste, hence it has been assumed that there will be no on-site vehicle movements for the assessment of night-time operational sound.

The noise assessment concluded that, for the closest residential receptors, the operational noise impact from the Facility will result in a negligible impact. Therefore, no mitigation measures are proposed other than those already embedded within the design of the Facility. Specific design mitigation measures will be subject to detailed design of the Facility, but the following sections describe general measures and techniques.

4.1.1.2 ERF Building Shell and Penetrations

Noise source: ERF building Shell and Sidewall Air Intakes/Exhausts

Type: Daytime and night-time operation and general noise, no tonal or impulse noise emanating from the building enclosure. A sound power level of 90 dBA (~80 dBA at 1m) was assumed in the modelling for any sidewall air intake/exhaust louvres.

Noise mitigation: The proposed noise mitigation measures for the ERF building are subject to detailed design of the Facility. However, the mitigation measures are expected to include an enclosed building using with standard industrial cladding (walls and roof) with acoustic louvres to mitigate the risk of noise 'break-out' or ensure the noise output with ventilation fans that are <85 dBA at 1m. The roof and façades of the main buildings will be constructed from insulated composite profiled cladding with a sound reduction index (RW) of 24dB.

4.1.1.3 ERF Main Stack Outlet (and ID Fan)

Noise source: ID fan and Stack

Type: Day and night-time operation. General broadband noise – no tonal noise is anticipated, however other characteristic sound from the stack has the potential to be readily distinctive against residual sound levels at night. A sound power level of 104 dBA (93 dBA at 1m) was assumed in the modelling for both point sources representing the ID fan system and the exhaust point from the main stack.

Noise Mitigation: The proposed noise mitigation measures for the ID fan are subject to detailed design of the Facility. It is expected that the ID fan will be located outside the ERF building next to the base of the main stack. It is anticipated that the stack will be fitted with a dedicated silencer. The stack will be designed to ensure that the flue gas flow rate is approximately 15 m/s but always less than 30 m/s (beyond which, in some circumstances, there can be a ‘whistle' from the top of the stack). The sound power rating of 104 dBA is expected to be achieved with standard fan systems however if this is not able to be achieved either an acoustical enclosure is required around the main fan with a in line silencer prior to the main stack is required or the selection of low noise equipment meeting this rating.

4.1.1.4 Turbine Hall

Noise source: Turbine Hall including generator within the hall.

Type: Day and night-time operation, potential tonal and general noise. Low frequency sound has been considered within the noise assessment and it was concluded that there will be no significant low frequency sound transmission through the building structure and that the proposed mitigation measures will provide the required level of attenuation for low frequency noise transmission. The following sound power levels were assumed in the modelling:

– Generator Enclosure Air Inlet with Silencer – 102 dBA
– Generator Enclosure Exhaust with Silencer – 102 dBA
– Turbine Combustion Air Inlet Stack with Silencer – 102 dBA
– Heat Recovery Steam Generator Stack with Silencer – 86 dBA
– Turbine Enclosure Exhaust with Silencer – 103 dBA

Noise mitigation: The proposed noise mitigation measures for the turbine hall are subject to detailed design of the Facility. However, the mitigation measures are expected to include constructing the turbine hall with materials which have sound reducing properties, such as concrete, or utilising acoustic cladding (walls and roof) to mitigate the risk of noise ‘break-out'. Further noise mitigation measures for the turbine hall may include acoustic doors (providing noise attenuation) kept shut except during maintenance or emergency occurrences, the use of a turbine table with mounts to reduce vibration and the location of the turbine hall providing further noise screening. It is expected that each intake and exhaust stack associated with both the HRGS, Turbine and Generator systems are equipped with silencers to achieve the maximum noise ratings detailed above.

4.1.1.5 ERF Waste Reception Area/Tipping Hall

Noise source: Tipping Hall with mobile plant and HGVs operating inside.

Noise type: Potential intermittent impulse noise offloading during daytime only, reversing alarms. A sound power level of 90 dBA (~80 dBA at 1m) was assumed in the modelling for the waste reception area for the tipping hall open bay doors.

Noise mitigation: Enclosed building using industrial cladding (walls and roof) with acoustic louvres to mitigate the risk of noise 'break-out'. The roof and façades of the main buildings would be constructed from insulated composite profiled cladding with a sound reduction index (RW) of 24dB assumed within the noise assessment.

The fast-acting automatic doors for the tipping hall and roller shutter doors and are understood to provide 10 dB and 18 dB noise attenuation respectively. GHD has conservatively assumed that 50% of the bay doors will be open at any one time and have modelled the breakout emissions from the open doors only.

4.1.1.6 Noise Associated with Operational ERF Emergency Steam Relief and Commissioning Steam Purging

Steam purging (or "steam blowing") is a critical hot commissioning activity that occurs once in the lifetime of the plant following first energization of the plant and following chemical passivation of the boiler internals. Its purpose is to "shock" and remove all internal piping corrosion and scale deposits between the boiler and the steam turbine inlet. The steam purge is a cyclical process of pressuring the boiler at high temperature and pressure. The steam is released in an uncontrolled manner to "blow" through the piping and systems over many cycles. This process, after chemical passivation of the boiler internals, can take up to 2 weeks to complete and is concluded when an adequate steam quality free of particulate/scale is achieved. The residues within the boiler during construction would causes damage to the steam turbine internal blades if not removed prior to the steam being passed to the turbine for the first time during commissioning. This process is achieved using a temporary commissioning dedicated sacrificial pipework system and silencer that is specifically installed for this process. For the avoidance of doubt, it is not possible to undertake steam purging during normal operation of the plant.

The boiler will be designed strictly in accordance with the Pressure Systems Safety Regulations which require any pressurised system to be fitted with emergency pressure relief valves to prevent over pressurisation and an uncontrolled rupture of the boiler. Pressure relief systems and valves are utilised for emergencies only and are not used for normal operation and control of the boiler meaning their use is to prevent an uncontrolled event. During any normal operation of the plant the pressure relief valves will not need to operate. In an exceptional circumstance (i.e., equipment failure elsewhere within the plant) the control system may not be able to prevent an over pressurisation of the steam system and the last line of defence is the pressure release valves within the boiler which will lift and vent the system pressure. The pressure relief cycle, if initiated, will last for approximately 4-6 minutes when normal operating pressure limits within the boiler are returned to 'normal' levels and safe shut-down or ongoing operations can be maintained. The pressure relief system will be fitted with silencer(s) specifically designed to reduce noise from this abnormal event to approximately 50 dB at the boundary of the ERF plant. It is understood from previous experience that it is simply not feasible to reduce noise levels below this level given the nature and requirement for this system to be safely effective.

The pressure relief valves will be safety tested on a periodic basis. The frequency of testing will be determined by the Pressure Equipment Directive written scheme of examination, defined within the UK pressure systems regulations. The frequency of testing will be determined by the written scheme of examination. The frequency of testing is usually between 12-24 months.

Steam purging is a planned event that will occur only during commissioning. Testing of the safety relief valves again is a planned operational activity with a frequency driven by legislation. All of these events will be planned to occur during day-time hours.

If there is an exceptional circumstance operationally where the plant control systems and operators cannot rectify an exceptional event, then an unplanned pressure relief event would occur for 2-4 minutes thereby avoiding a significant incident and risk to personnel safety.

Taking this into consideration and in conclusion, following commencement of operation of the Facility, steam purging will not occur during operation of the Facility. If there is an over pressurisation and uncontrolled event within the pressurised boiler, the pressure relief valve system will function to release the pressure to safe levels within the boiler. If the cause of the over pressurisation has been understood, resolved and stable conditions resumed within the boiler then normal operation will resume. However, if the cause of the over-pressurisation is not resolved, the boiler will shut down safely to enable the issue to be investigated and resolved prior to restarting the plant.

4.1.2 Bottom Ash Handling Building (BAH)

Noise source: Bottom Ash Storage Bay Doors, Sidewall Louvres and Rubble Master

Type: Noise from conveyors generating low-level broad-spectrum noise levels which will not be tonal or impulsive (broadband only). A sound power level of 107.5 dBA was assumed in the modelling for the open bay doors and a sound power level of 112.4 dBA was used for the Rubble Master (mobile Crusher) located outside the building. A sound power level of 90 dBA (~80 dBA at 1m) was assumed in the modelling for any sidewall air intake/exhaust louvres.

Noise mitigation: Enclosed building using standard cladding (walls and roof) with acoustic louvres to mitigate the risk of noise ‘break-out'. The roof and façades of the main buildings would be constructed from insulated composite profiled cladding with a sound reduction index (RW) of 24dB assumed within the noise assessment. The sound power levels modelled for the Rubble Master are expected to be the maximum not to exceed values for this equipment/operation. Should this not be practical then lower noise equipment or on-site berms/barriers would be required to block noise emissions to the sensitive receptors to the west of the BAH facility.

4.1.3 Fire Pump Building (FPB)

Noise source: Fire Pump Building Ventilation Systems

Type: Noise from fire pump systems generating low-level broad-spectrum noise levels which will not be tonal or impulsive (broadband only). A sound power level of 97 dB was assumed in the modelling for the fire pump exhaust with a silencer and a sound power level of 92 dBA was used for the fire pump systems sidewall air intake with an acoustical louvre located on the side of the building.

Noise mitigation: Enclosed building using standard cladding (walls and roof) with acoustic louvres to mitigate the risk of noise ‘break-out'. The roof and façades of the main buildings would be constructed from insulated composite profiled cladding with a sound reduction index (RW) of 24dB assumed within the noise assessment. It is expected that each intake and exhaust stack associated with fire pump systems are equipped with silencers/acoustic louvres to achieve the maximum noise ratings detailed above.

4.1.4 Green Waste Facility (GWF)

Noise sources: Mobark 950 Tub Grinder, Komptech Shredder, Screener & Front-End Loader.

Type: Noise from grinding, screening and shredding systems generating low-level broad-spectrum noise levels which will not be tonal or impulsive (broadband only). A sound power level of 112 dBA was assumed in the modelling for the Screener and Shredder and 114 dBA for the Grinder based on each unit operating 30 minutes per hour during the day.

Noise mitigation: As these significant noise sources have line of sight and exposure to NSR3 and NSR5 GHD recommends re-orientating the GWF operations pad to use the proposed storage area concrete push walls (4.9m

above grade) to block line of sight and noise emissions. Yellow lines represent the new location for the existing green push walls as detailed below:

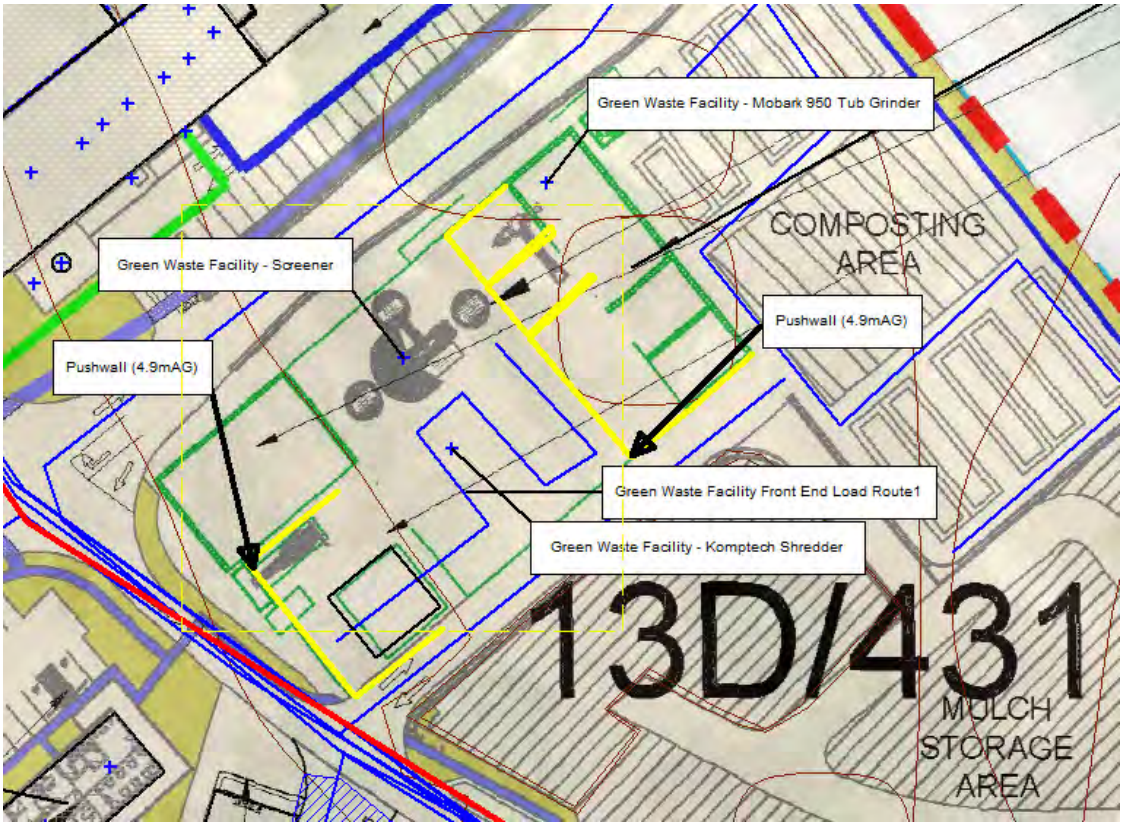

Figure 5 Proposed GWF Equipment/Pad Orientation

It is expected that this equipment and orientation of the operations pad are subject to change but these general recommendations on noise mitigation should be reviewed and re-evaluated during detailed design.

4.1.5 Materials Recycling Facility Building (MRF)

Noise source: MRF Building, Bay Doors and Glass roll off bin.

Type: Noise from inside the MRF building will be generating low-level broad-spectrum noise levels which will may be tonal or impulsive (broadband only). A sound power level of 107.5 dB was assumed in the modelling for the open bay doors and a sound power level of 117 dBA (including penalty adjustments) was used for the raw glass falling into Roll off Bin located outside the building which was assumed to operate 30 minutes out of each hour during the daytime only.

Noise mitigation: Enclosed building using standard cladding (walls and roof) with acoustic louvres to mitigate the risk of noise ‘break-out'. The roof and façades of the main buildings would be constructed from insulated composite profiled cladding with a sound reduction index (RW) of 24dB assumed within the noise assessment. The sound power levels modelled for the air intakes on the side of the building and glass roll off bin are expected to be the maximum not to exceed values for this equipment/operation. Should this not be practical then lower noise equipment would be required to block noise emissions to the sensitive receptors to the west and south of the MRF facility.

Additionally, a noise barrier is required to protect noise emissions toward the south by erecting a 4.9m tall, 6m long noise barrier (yellow line) at the position shown on the figure below to provide reduced line of sight and noise towards NSR3 to the southeast:

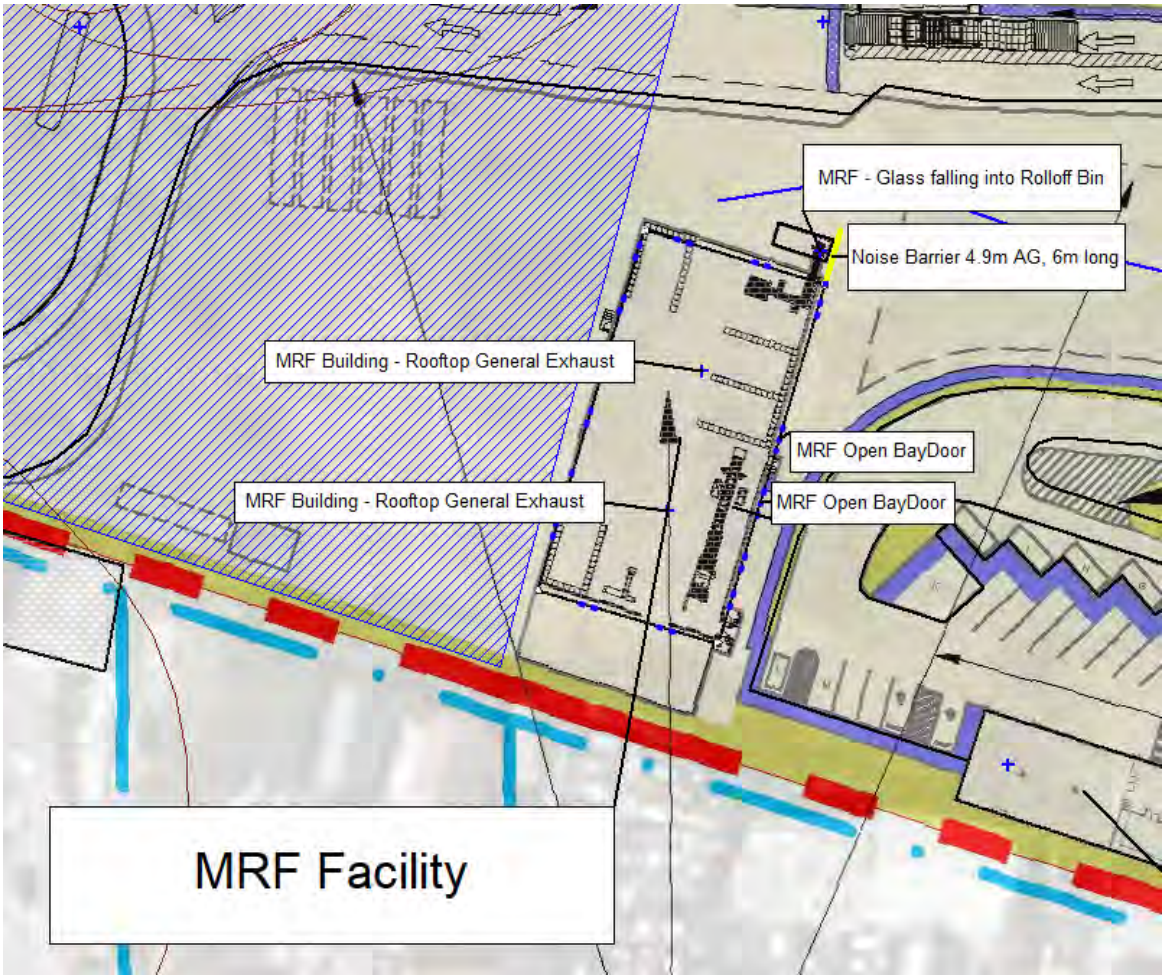

Figure 6 Proposed MRF Noise Barrier Detail

4.2 Noise Source Summary

The Applicant is proposing to construct and operate an ISWMS which will incorporate various on-site buildings, operations and energy from Waste systems in addition to the landfilling activities which each have the potential to cause an adverse noise impact at receptors.

This NVIA focuses on the sound emissions from the significant noise sources identified at the ISWMS with the potential to adversely impact the sensitive receptors. The significant noise sources are identified in the Noise Source Summary Table C.1 of Appendix C. The noise source locations are shown in in Figures A.1A – A.1G in Appendix A.

4.2.1 Sitewide Outdoor Truck and Heavy Equipment Volumes

Onsite outdoor truck and heavy equipment activities for operations as well as shipping/receiving loading is summarized in Table 15 below:

Table 15 Sitewide Outdoor Truck and Heavy Equipment Volumes

Type of Vehicle/Description	ISWMS Building/Area	Noise Source ID	Day (07:00 – 19:00) Vehicles / hour	Evening (19:00 – 23:00) Vehicles / hour	Night (23:00 – 07:00) Vehicles / hour
ERF- Inbound/Outbound Truck Route	ERF	ERF_TR1	5	0	0
Green Waste Facility Front End Load Route 1	GWF	GWF_Loader1	20	0	0
Green Waste Facility Front End Load Route 2	GWF	GWF_Loader2	20	0	0
Green Waste Facility - Inbound/Outbound Truck Route	GWF	GWF_TR1	1	0	0
MRF - Forklift Moving Bails Route1	MRF	MRF_Forklift1	10	0	0
ELV - Inbound/Outbound Truck Route	ELV	ELV_TR1	2	0	0
Maintenance Bldg. - Inbound/Outbound Truck Route	Maintenance	Main_TR1	1	0	0
C&D and BAF - Inbound/Outbound Truck Route	CD	CD_BAF_TR1	6	0	0
Medical Waste Bldg. - Inbound/Outbound Truck Route	MW	MW_TR1	1	0	0
Phase 2 Final Landfill Cell - Inbound/Outbound Truck Route	Phase 2 Landfill Cell	S_TR1	13	0	0
Household Waste Recycling Centre – Container Movements	Household Waste Recycling Center	HW_TR1	4	0	0

Note: Noise Source Vehicle routes are identified in Figure A.1D in Appendix A.

Vehicle deliveries and collections will also contribute to the noise climate. However, vehicle movements to and from the site are not considered to significantly impact on road traffic noise levels.

The significant equipment sources are all either trucking related activities, building penetrations, rooftop equipment or outdoor equipment located beside the buildings. Noise predictions are based on noise data provided by the Client as detailed in Section of this report for the various processes anticipated within the ISWMS buildings.

GHD determined that with standard industrial building construction that the building cladding would be an insignificant source of noise and were therefore not modelled in detail as they would provide a minimum sound insulation of 24 dB Rw resulting in minimal off-site impacts.

The existing buildings at the Site are made of standard industrial construction materials. The other noise sources at the Facility have not been included since they are considered insignificant contributors to the overall Facility noise level at the sensitive receptors which are expected to contribute less than 25 dBA at the worst-case receptor.

Some of the proposed ISWMS buildings do have significant interior noise sources resulting in breakout noise from passive sidewall air intake louvres, exhaust points and open bay doors which were modelled in detail.

Noise radiating through the passive louvres or bay doors were modelled as point sources or vertical area source. GHD expects that the Facility will provide GHD with updated equipment selections and specifications following final

selection of any proposed equipment to confirm that the noise levels meet the maximum not to exceed noise criteria as specified in this NVIA by proper selection or equivalent noise mitigation measures.

A detailed summary of sound power levels in full octave band centre frequencies for the equipment is presented in Table C.1 of Appendix C.

Noise level checks may be carried out regularly in operational areas where high noise levels may be present, with early warning of increasing noise levels resulting in a noise reduction or mitigation program.

Each potential source of significant operational noise is identified below for each building/operational area:

4.2.2 Energy Recovery Facility (ERF)

The ERF area of the main building includes the following significant outdoor noise sources:

– 1 x Turbine Hall Generator Air Inlet Stack (103 dBA)
– 1 x Turbine Hall Generator Air Exhaust Stack (103 dBA)
– 1 x Turbine Hall Combustion Air Inlet Stack (103 dBA)
– 1 x Turbine Hall Heat Recovery Steam Generator Stack (86 dBA)
– 1 x Turbine Hall Turbine Enclosure Exhaust Stack (103 dBA)
– 1 x Turbine Hall After Cooler (96 dBA)
– 1 x Turbine Hall Oil Cooler (96 dBA)
– 1 x Air Cooled Condenser Unit (97 dBA)
– 14 x Air Sidewall Intake/Exhaust Louvres (96 dBA)
– 2 x Tipping Hall Bay Doors – Open (90 dBA)
– 1 x Silo Loading - Blower Truck (106 dBA)
– 2 x Compressor Intake Louvre (97 dBA)
– 2 x Compressor Exhaust Louvre (97 dBA)
– 2 x Rooftop General Exhaust Fans (85 dBA)
– 1 x Main Stack ID Fan (104 dBA)
– 1 x Main Stack Exhaust (104 dBA)

4.2.3 Site Weighbridges

The weighbridge area includes the following significant outdoor noise sources:

– 2 x Idling Trucks (96 dBA) – Day Only

4.2.4 Green Waste Processing Facility

The Green Waste Processing Facility includes the following significant outdoor noise sources:

– 1 x Komptech Shredder (112 dBA) – Day Only (30 mins/hr)
– 1 x Mobark 950 Tub Grinder (114 dBA) – Day Only (30 mins/hr)
– 1 x Screener (112 dBA) – Day Only (30 mins/hr)
– 1 x Front End Loader Route 1 on Shredder Pad (20 trips/hr) – Day Only
– 1 x Front End Loader Route 2 in Composting area (20 trips/hr) – Day Only

4.2.5 Construction and Demolition Waste Processing Facility

The Construction and Demolition Waste Processing Facility includes the following significant outdoor noise sources:

– 2 x Rooftop General Exhaust Fans (85 dBA)
– 2 x Bay Doors – Open (108 dBA) – Day only
– 4 x Sidewall Exhausts (85 dBA)
– 1 x Front End Loader Operating in Material Handling Area (104 dBA)
– C&D and BAF - Rubble Master (Mobile Crusher) (112 dBA) – Day Only (30 mins/hr)

4.2.6 Bottom Ash Processing Facility

The Bottom Ash Processing Facility includes the following significant outdoor noise sources:

– 2 x Rooftop General Exhaust Fans (85 dBA)
– 2 x Bay Doors – Open (108 dBA) – Day only
– 4 x Sidewall Air Intake Louvre (96 dBA)
– 1 x Front End Loader Operating in Material Handling Area (104 dBA)

4.2.7 Abandoned and End-of-Life / Scrap Metal Processing Facility

The Abandoned and End-of-Life / Scrap Metal Processing Facility includes the following significant outdoor noise sources:

– 2 x Rooftop General Exhaust Fans (85 dBA)
– 2 x Bay Doors – Open (98 dBA) – Day only
– 1 x Torch Cutting Area (100 dBA) – Day only
– 1 x Hydraulic Shear/Baler (107 dBA) – Day only
– 1 x Excavator w/ Grapple Moving Vehicles (100 dBA) – Day only
– 1 x Idling Truck (96 dBA) – Day Only
– 1 x Front End Loader Operating in Material Handling Area (104 dBA)

4.2.8 Medical Waste Facility

The Medical Waste Facility includes the following significant outdoor noise sources:

– 2 x Rooftop HVAC (86 dBA)

4.2.9 Materials Recycling Facility

The Materials Recycling Facility includes the following significant outdoor noise sources:

– 2 x Rooftop HVAC (86 dBA)
– 2 x Bay Doors – Open (98 dBA) – Day only

4.2.10 Household Waste Recycling Centre

The Household Waste Recycling Centre includes the following significant outdoor noise sources:

– 2 x Rooftop HVAC (86 dBA)

4.2.11 Landfill Gas Facility

The Landfill Gas Facility includes the following significant outdoor noise sources:

– 1 x Landfill Gas Flare System (95 dBA)

4.2.12 Admin Building

The Admin Building includes the following significant outdoor noise sources:

– 2 x Rooftop HVAC (86 dBA)

4.2.13 Maintenance Building

The Maintenance Building includes the following significant outdoor noise sources:

– 2 x Rooftop HVAC (86 dBA)
– 2 x Bay Doors – Open – Impact Guns, Air Compressors (112 dBA) – Day only

4.2.14 Future Phase 2 Residual Waste Landfill Operations

The Phase 2 Residual Waste Landfill Operations includes the following significant outdoor noise sources:

– 1 x Bulldozer (106 dBA) – Day only
– 1 x Landfill Compactor (103 dBA) – Day only
– 1 x Landfill Excavator Unloading Trucks (110 dBA) – Day only

4.2.15 Construction Noise Source Summary

Equipment and activities associated with Phases 1 to 3 for the construction of the ISWMS (Project) have the potential to produce noise emissions in the vicinity of the Project above the documented baseline limits. Changes to ambient noise levels and vibrations have the potential to impact existing sensitive receptors. The construction phase of any project is typically considered temporary or short-term relative to the entire life cycle of a project and mostly limited to daytime construction hours. It is anticipated that any construction or operational noise will be at or below the BS threshold limits at the worst-case receptor locations. Should levels above the threshold limits occur, noise mitigating controls will be considered.

The following section details an updated analysis, parameters or assumptions used in the noise evaluation of the construction noise analysis.

Noise Source Operating Parameters/Assumptions

In order to predict the future worst-case noise impacts from the Project activities, representative octave band noise data was used or measured from construction/processing equipment similar to what is noted to be required for the Project. This data was obtained from the tables in the annexes of BS 5228-1:2009+A1:2014. GHD's noise source library was used as a supplemental document to obtain sound level data for equipment not listed in the BS5228-1 Standard.

Annex F of BS5228-1 specifies in its calculation method that the sound power levels of equipment should be adjusted based on the expected percentage of time that the equipment will actually be operational and emitting significant noise. This was accomplished using the "Acoustical Usage Factors" obtained from the United States Department of Transportation, Federal Highway Administration (FHWA) document FHWA Roadway Construction Noise Model User's Guide, 2006. If an acoustical usage factor was not available, the default value of 50% is used.

The equipment to be used during each phase of construction is listed in the tables below, along with their sound power levels and acoustical usage factors.

Table 16 Estimated Sound Power Level and Equipment List for Each Phase of Construction

Equipment	Sound Power Level (dBA)	Acoustical Usage Factor	Phase 1 – Earthworks	Phase 2 – Piling / Concrete	Phase 3 – MEP / Paving
Angle Grinder	112	50%			4
Backhoe	98	40%	1		1
Bulldozer	106	40%	1		1
Concrete Saw	124	20%		5	2
Compactor	112	20%	1		
Concrete Mixer (Small)	93	50%		3	3
Concrete Mixer Truck	111	40%		8	
Concrete Pump (Truck)	111	20%		4	
Core Drill	116	50%		5	1
Crane (150 Ton)	109	16%	1	1	1
Crane (60 Ton)	108	16%	1	1	1
Crane (30 Ton)	101	16%	1	1	1
Dump Truck	116	40%	3	3	3
Drill Rig	105	20%	5	5	
Excavator	108	40%	1	1	1
Excavator (Mini)	99	40%		4	2
Skid Steer	110	40%	2		
Fuel Tanker Lorry	107	50%			2
Gas Cutter	96	40%		5	
Generator	105	50%	1	2	5
Grader	117	40%	1		
Loader	110	40%			4
Hammer Rig (Piling)	120	20%		4	
Paver	115	50%			2
Pneumatic Tool	117	50%			5
Poker Vibrator	110	50%		5	
Road Planer	113	50%			3
Road Planer (Mini)	98	50%			2
Roller	105	20%	1		2
Scissor Lift	98	50%			1
Telescopic Handler	110	50%			1
Water Pump	96	50%		1	1
Welder	105	40%		5	5
Wheel Wash Station	103	50%	1	1	1

There are no other significant noise generating activities or equipment.

Figures A.1E to A1.G have been created to show the noise source locations during each phase of construction. These figures can be found in Appendix A.

4.3 Assessment of Effects

4.3.1 Impact of the Operations Associated with the ISWMS

Noise modelling has been undertaken to predict the noise emissions from the ISWMS at receptors. The predicted noise levels of each process within the ISWMS buildings, operations and vehicle movements have been calculated to provide the total cumulative noise level at each receptor, during typical daytime and night-time periods.

The noise modelling considers that most onsite buildings and operations operate during the daytime only, landfill operates during the daytime and evening, and the ERF process equipment and main stack operates continuously.

The results of the modelling for the operation of the site wide ISWMS at each receptor are shown in Table 17:

Table 17 Predicted Noise Levels Generated by the Operations of the ISWMS at Sensitive Receptor Locations

NSR	Day (07:00 – 18:00) (dBA 1 hr L_{Aeq})	Evening (18:00 – 23:00) (dBA 1 hr L_{Aeq})	Night (23:00 – 07:00) (dBA 1 hr L_{Aeq})
NSR1 – Lakeside Development (7.5 metres above grade [m AG])	56	40	40
NSR2 – Residence on Parkside Cl. (4 m AG)	39	31	31
NSR3 – Residence on Seymour Rd. (1.5 m AG)	52	45	45
NSR4 – Cayman International School (4.5 m AG)	39	29	29
NSR5 – Residence on Woodlake Drive (1.5 m AG)	56	47	47
NSR6 - Proposed New Health City Camana Bay Medical Campus (7.5m AG)	42	35	35

4.3.2 Off-Site Vehicle Movements due to Operations of the ISWMS

There will be additional traffic movements as a result of the proposed ISWMS. Following a review of the information from the National Roads Authority of the Grand Cayman and traffic count data from APEC, the increase in traffic is understood to be approximately 2% on the sections of the Esterly Tibbetts Highway to the west. The increase in HGVs is understood to be around 3% on the section of the North Sound Road to the southwest of the ISWMS and up to 16% on the sections of the Seymour Road to the southeast of the ISWMS.

The Design Manual for Roads and Bridges (DMRB) Volume 11 Section 3 Part 7 HD 213/11 defines the threshold for determining whether a traffic noise assessment is required. If during the daytime and night-time period there is a permanent change in magnitude of 3 dB(A) in the long term (typically 15 years after project opening), then a detailed assessment is required. HD213/11 Chapter 3 Table 3.2 defines a change in noise of 3 dB(A) or less has a negligible

impact in the long term. HD213/11 Annex 1 – Assessment Approach paragraph A1.8(ii) states that "a change in noise level of 3 dB(A) is equivalent to a 100% increase… in traffic flow".

Table 18 Operational Route Traffic Noise Change Due to Operations Traffic

Noise Sensitive Receptor	Existing 18 hr Operational Route Traffic Noise (dBA)	Operational 18 hr Haul Route Traffic Noise (dBA)	Change Due to Operation (dBA)	Long-Term Magnitude of Impact
Seymour Rd	65.4	67.9	2.5	Negligible
N Sound Rd. (West)	71.3	72.8	1.5	Negligible
N Sound Rd. (East)	70.6	72.4	1.8	Negligible
Thomas Russel Ave.	75.8	76.1	0.3	Negligible
Elgin Ave.	71.4	72.2	0.8	Negligible
Goring Ave.	71.4	72.2	0.8	Negligible
Harbour Dr.	74.0	74.4	0.4	Negligible
Esterly Tibbets Highway	76.7	77.0	0.3	Negligible

A 2 to 3% increase in traffic flow to the primary and secondary arterials around the site and 16% increase in traffic flow to the collector roads would cause a change of noise level approximately in the order of 3 dB(A) or less on the road network leading away from the site entrance. The impact of increased traffic can be considered to be negligible and has not been assessed further in the long-term.

4.3.3 Noise Impact Assessment - BS4142 Assessment

In accordance with BS4142, an industrial noise assessment has been carried out to assess the impact of sound from the proposed ISWMS on existing sensitive receptors.

4.3.3.1 Rating level

Acoustic Feature Correction

BS4142 includes guidance on the application of an additional weighting which should be applied to the specific sound level should the industrial noise be tonal, impulsive, or intermittent, as experienced at proposed receptors.

All proposed plants operations would run continuously during their periods of operations and therefore no penalty for impulsivity or intermittency has been applied. It is assumed all proposed plants within the ISWMS would be designed with mitigation, such that sound breakout would not be tonal at the existing sensitive receptors. Therefore, no correction has been applied to the specific sound level.

All HGV movements at the facility would be similar to road traffic on the Esterly Tibbetts Highway, which is the dominant noise source heard at all receptors. Therefore, no penalty has been applied to the specific sound level.

Selection of the Background Sound

Section 8 of BS4142 provides guidance on the selection of the background sound to be used in the assessment. BS4142 states that the background sound levels should be representative of the period being assessed (i.e., daytime or night-time periods), and that there is no "single" background sound level.

For the purpose of the assessment the range of background sound levels during the day and night-time periods, measured at monitoring locations 1-4, have been used. The data collected and presented within Section 1.5.3 of this Study details the representative $L_{A90,11hour}$ daytime, $L_{A90,5hour}$ evening and $L_{A90,8hour}$ night-time, background sound levels at existing sensitive receptors.

4.3.3.2 Comparison of the Background Sound and Rating Levels

Daytime Assessment

In accordance with BS4142, the rating level of industrial noise at the existing receptors has been compared with the representative background sound levels. HGV deliveries and most operations associated with the ISWMS will cease at approximately 18:00, therefore, a separate assessment has been undertaken for daytime (07:00 - 18:00) evening (18:00-23:00), and night-time (23:00-07:00). The results for each receptor location are shown in Table 19, Table 20 and Table 21 for the daytime, evening and night-time period respectively.

Table 19 Comparison of Rating Level and Background Sound Levels for Daytime Operations (07:00 and 18:00)

NSR	NSR1 – Lakeside Development	NSR2 – Residence on Parkside Cl	NSR3 – Residence on Seymour Rd.	NSR4 – Cayman International School	NSR5 – Residence on Woodlake Drive	NSR6 – Proposed New Health City Camana Bay Medical Campus
Modelled ISWMS Daytime Noise Level, 1-hour L_{Aeq} (dBA)	56	40	52	39	56	42
Acoustic Feature Correction	0	0	0	0	0	0
Calculated Rating Level (dBA)	56	40	52	39	56	42
Measured Background Sound Level at Each Receptor Location $LA90_{11\ hour}$ (dBA)	51-59	43-46	53-57	43-52	51-59	43-52
Lowest Excess of rating over Background level	-3	-6	-5	-13	-3	-10
Highest Excess of rating over Background level	5	-3	-1	-4	5	-1

Table 20 Comparison of Rating Level and Background Sound Levels for Evening Operations (18:00 and 23:00)

NSR	NSR1 – Lakeside Development	NSR2 – Residence on Parkside Cl	NSR3 – Residence on Seymour Rd.	NSR4 – Cayman International School	NSR5 – Residence on Woodlake Drive	NSR6 - Proposed New Health City Camana Bay Medical Campus
Modelled ISWMS Evening Noise Level, L_{Aeq} (dBA)	43	33	46	32	50	35
Acoustic Feature Correction	0	0	0	0	0	0
Calculated Rating Level (dBA)	43	33	46	32	50	35

NSR	NSR1 – Lakeside Development	NSR2 – Residence on Parkside Cl	NSR3 – Residence on Seymour Rd.	NSR4 – Cayman International School	NSR5 – Residence on Woodlake Drive	NSR6 - Proposed New Health City Camana Bay Medical Campus
Measured Background Sound Level at Each Receptor Location LA90 $_{5\ hour}$ (dBA)	49-54	40-43	52-54	42-45	49-54	42-45
Lowest Excess of rating over Background level	-11	-10	-8	-13	-4	-10
Highest Excess of rating over Background level	-6	-7	-6	-10	1	-7

Table 21 Comparison of Rating Level and Background Sound Levels for Night-time Operations (23:00 and 07:00)

NSR	NSR1 – Lakeside Development	NSR2 – Residence on Parkside Cl	NSR3 – Residence on Seymour Rd.	NSR4 – Cayman International School	NSR5 – Residence on Woodlake Drive	NSR6 - Proposed New Health City Camana Bay Medical Campus
Modelled ISWMS Night-Time Noise Level, L_{Aeq} (dBA)	43	33	46	32	50	35
Acoustic Feature Correction	0	0	0	0	0	0
Calculated Rating Level (dBA)	43	33	46	32	50	35
Measured Background Sound Level at Each Receptor Location LA90 $_{8\ hour}$ (dBA)	45 - 47	36-40	49-53	38-41	45 - 47	38-41
Lowest Excess of rating over Background level	-4	-7	-7	-9	3	-6
Highest Excess of rating over Background level	-2	-3	-3	-6	5	-3

The results in Table 19, Table 20 and Table 21 indicate that during the daytime, evening and night-time hours, the predicted rating level likely to be generated by the operations of the proposed ISWMS development will be below the

highest existing background noise level at all existing sensitive receptor locations during all periods with the exception of NSR 5 (Woodlake Dr.). NSR5 may experience +3 dBA impacts over the highest background during the night.

Where the rating level does not exceed the background sound level, this is an indication of the specific sound source having a low impact, depending on the context. However, during the quieter periods of the daytime, evening and night-time, the predicted rating level likely to be generated by the operations of the proposed development will be above the lowest background noise level at NSR1 and NSR5 during the day by +5 dBA. Additionally, NSR5 may have noise impacts above the lowest background noise level of + 1 dBA during the evening and by +5 dBA during night-time. In accordance with BS4142, a difference of around >5 dB is an indication of an adverse impact, and +10 dB is likely to be an indication of a significant adverse impact, depending on context.

In accordance with BS4142 an assessment of the context in which the industrial sound resides must be undertaken to determine the potential noise impact.

4.3.3.3 BS4142 Context Assessment

BS4142:2014 states "The significance of sound of an industrial and/or commercial nature depends upon both the margin by which the rating level of the specific sound sources exceeds the background sound level and the context in which the sound occurs".

The first requirement of this statement has been determined within the noise impact assessment section above. To determine the context in which the industrial sound will reside, three factors must be considered, these are:

– The absolute level of sound
– The character and level of the residual sound compared to the character and level of the specific sound
– The sensitivity of the receptor

Absolute Level of Sound

To determine the first context test in BS4142 it is necessary to determine whether the residual and background sound levels are high or low. Section 11 of BS4142 states:

> *"Where background sound levels and rating levels are low, absolute levels might be as, or more, relevant than the margin by which the rating level exceeds the background. This is especially true at night.*
>
> *Where residual sound levels are very high, the residual sound might itself result in adverse impacts or significant adverse impacts, and the margin by which the rating level exceeds the background might simply be an indication of the extent to which the specific sound source is likely to make those impacts worse."*

As shown in Tables 19, 20 and 21 (Comparison of Rating Level and Background Sound Levels), the background sound levels and rating levels at each receptor are relatively high. Therefore, in accordance with BS4142, the absolute level is as, or more, relevant when establishing a potential impact.

In order to assess the proposed ISWMS in the context of its environment and that of each of the existing sensitive receptors, the predicted specific sound level from the ISWMS have been added to the measured average ambient noise levels to give the absolute level of noise at receptors with the ISWMS operating.

This future absolute noise level has been compared against the existing ambient noise level, and the predicted change in noise has been stated. The results for the NSR's for daytime, evening and night-time periods are detailed within Tables 22, 23 and 24 respectively.

Difference between existing ambient sound levels and predicted future sound levels	0	0	0	0	0	0

The assessment of the absolute level of noise shows that the proposed ISWMS will not lead to any increase in the existing ambient noise levels at the nearby sensitive receptors during the daytime period with the exception of NSR1 and NSR5 which may experience up to +1 dBA when adding the ISWMS impacts to the existing background.

The assessment of the absolute level of noise shows that the proposed ISWMS will not lead to any increase in the existing ambient noise levels at the nearby sensitive receptors during the evening and night-time period.

A change in noise of up to 3 dBA is generally regarded as a negligible change and not perceivable by most people. Therefore, it is unlikely that this increase will be noticeable to residents. This is a positive indication that noise from the ISWMS will not be significant at the existing sensitive receptor locations.

Therefore, the potential noise impact of the ISWMS at NSRs is likely to be less than is suggested by Tables 19, 20 and 21 (Comparison of Rating Level and Background Sound Levels).

Character and Level of Residual and Specific Sound

The character of the residual sound, which contains mid frequency noise from road traffic and industrial noise from the existing industrial area to the south and Esterly Tibbetts Highway to the east means that the character of the specific sound of the proposed development will be very similar to existing conditions and in keeping with the immediate area.

The assessment shows that the average level of the residual sound and the calculated level of the specific sound are similar. In addition, they are both considered to be relatively high.

This is a positive indication that the noise impact from the proposed development would be less than is suggested by 19, 20 and 21 (Comparison of Rating Level and Background Sound Levels).

Sensitivity of Receptor and Existing Acoustic Conditions

With regard to pertinent factors to be taken into consideration, Section 11 of BS4142 states;

> *"The sensitivity of the receptor and whether dwellings or other premises used for residential purposes will already incorporate design measures that secure good internal and/or outdoor acoustic conditions, such as:*
>
> *i. façade insulation treatment;*
> *ii. ventilation and/or cooling that will reduce the need to have windows open so as to provide rapid or purge ventilation;*
> *iii. and acoustic screening."*

The proposed receptors will have moderate sensitivity given their residential nature, as in accordance with Table 3, except for NSR4 and NSR6 which are high sensitivity.

Additionally, there appears to be no screening or shielding effect of the proposed ISWMS for sensitive receptors at the residential locations.

Summary of BS4142 Context Assessment

The context assessment shows that the measured, existing ambient sound level is very similar to the predicted ambient sound level with the ISWMS in place and that the character of the specific sound is very similar to the residual sound in the surrounding area. It can be concluded that the effect of the proposed development is overstated slightly by the exceedance of the background noise levels by the specific noise from the proposed ISWMS.

In order to determine the significance of the noise levels with the proposed ISWMS in place, the absolute noise levels have been compared to guideline noise levels, as detailed in BS8233.

4.3.3.4 BS8233 Context Assessment

Based on site observations and local knowledge, some existing sensitive receptors appear to be naturally ventilated with no specific mitigation measures to control noise ingress from the surrounding area with the exception of the Cayman International School and the proposed New Health City Medical Campus which were assumed to be climate-controlled buildings with closed windows providing 23 dBA attenuation. For the purpose of the assessment, it was conservatively assumed that of the residential areas will have windows open and the attenuation provided by the façade will be approximately 13 dBA.

In order to assess the proposed ISWMS in the context of its environment and that of each of the existing sensitive receptors, a comparison of the absolute noise level and guideline noise levels has been undertaken, for both external and internal living areas, as shown in Table 25 and Table 26 below.

Table 25 Comparison of Absolute Noise Levels at Sensitive Receptor Locations and Guideline Noise Levels – External Areas

NSR	NSR1 – Lakeside Development Day (07:00 – 18:00) (dB $L_{aeq\ 11hr}$)	NSR2 – Residence on Parkside Cl. Day (07:00 – 18:00) (dB $L_{aeq11hr}$)	NSR3 – Residence on Seymour Rd. Day (07:00 – 18:00) (dB $L_{aeq11hr}$)	NSR4 – Cayman International School Day (07:00 – 18:00) (dB $L_{aeq11hr}$)	NSR5 – Residence on Woodlake Drive Day (07:00 – 18:00) (dB $L_{aeq11hr}$)	NSR6 - Proposed New Health City Camana Bay Medical Campus

Table 25 shows that during the daytime, in external areas, the absolute sound level would above the upper guideline noise level of 55 dB(A) and above the desirable noise guideline level of 50dB(A) at all NSRs. However, as shown in Table 22 (Context Assessment at Existing Sensitive Receptors), the measured ambient noise levels at all receptors are close to the same or less than the absolute level shown in Table 25 above. Therefore, the impact of the ISWMS is negligible.

Table 26 above shows that during the daytime, evening and night-time, with windows open, the absolute sound level would exceed internal noise guideline levels in living rooms and bedrooms of NSRs. However, as shown in Table 22 (Context Assessment at Existing Sensitive Receptors), the measured ambient noise levels at all receptors already exceed internal noise levels, without the proposed ISWMS in place, and therefore the impact of the ISWMS is negligible.

Taking this context into consideration, the impact at the NSR's during the daytime, evening and night-time is considered is likely to be significantly less than is suggested in Tables 19, 20 and 21 (Comparison of Rating Level and Background Sound Levels).

4.3.3.5 Summary of BS4142 Assessment

In summary, we have found that noise from the ISWMS, on occasions, would exceed the background sound level at receptors. However, both the background sound levels are low, and noise from the ISWMS will not significantly change the existing ambient sound levels at receptors. In addition, noise from the ISWMS is thought to be in keeping with the character of noise at the receptors. Ambient noise levels which include noise from the ISWMS, are significantly above the internal and external noise guideline levels stated in BS8233 when considering a conservative attenuation scenario of open windows.

Therefore, when considering the context of the sound from the ISWMS, the overall noise impact is considered to be low during the daytime and medium moderate during the quiet parts of the evening and night-time.

In any case, mitigation measures will be incorporated into the site design to reduce noise emissions where feasible and Best Available Technology (BAT) will be adopted, which will further reduce noise from the ISWMS at receptors.

The affected sensitive receptors are considered to be of medium and high sensitivity in accordance with Table 3. It is considered that the magnitude will be low in accordance with Table 2 as the activities will cause a change in the baseline environment and may cause an exceedance of guideline objectives. The impact is therefore considered to be moderate, however with mitigation measures in place the impact is seen as minor or negligible.

4.3.4 Construction Noise Assessment

It is expected that noise generated during the construction phase will propagate beyond the site boundary and be audible at the nearest NSRs.

The amount and types of equipment used in the construction of the ISWMS will change over the construction process, and so the profile of the noise propagating off-site will also change. In order to capture the changing noise profile, three evaluations were done at three different phases of construction, with different equipment being used in each evaluation, representing the worst-case months (most equipment) during the different phases:

1. Phase 1 – Earthworks
2. Phase 2 – Piling and Concrete Works
3. Phase 3 – MEP (Mechanical, Electrical, Plumbing), Paving, Completion of Concrete

Construction is planned to occur during daytime hours, with after-hours work reserved for limited, low-noise work. The equipment is classified as "stationary sources" of sound.

The worst-case assessment of steady-state noise sources at the selected points-of-reception was based on measured sound pressure levels. CadnaA Acoustical Modelling Software (CadnaA), version 2023, was used to model the potential impacts of the significant construction noise sources.

The magnitude of noise impacts associated with construction will be dependent upon a number of factors including:

– The intensity of construction activities
– The location of construction activities
– The type of equipment used
– Existing local noise sources
– Intervening terrain
– The prevailing weather conditions

The resulting noise levels at the NSRs and the corresponding impact during each phase are shown below:

Table 27 Resulting Noise Levels for Each Phase of Construction at Each NSR

Worst-case NSR	Phase 1 (Earthworks)		Phase 2 (Piling / Concrete)		Phase 3 (MEP / Paving)	
	Predicted Level (dBA)	Magnitude of Change	Predicted Level (dBA)	Magnitude of Change	Predicted Level (dBA)	Magnitude of Change
NSR1 – Lakeside Development (7.5 m AG)	51	Very Low	58	Low	59	Low
NSR2 – Residence on Parkside Cl. (4 m AG)	41	Very Low	49	Very Low	49	Very Low
NSR3 – Residence on Seymour Rd. (1.5 m AG)	48	Very Low	55	Very Low	56	Low
NSR4 – Cayman International School (4.5 m AG)	38	Very Low	46	Very Low	47	Very Low
NSR5 – Residence on Woodlake Drive (1.5 m AG)	55	Very Low	63	Low	63	Low
NSR6 – Hospital on Minerva Drive (7.5 m AG)	45	Very Low	54	Very Low	54	Very Low

The modelled noise impacts associated with each stage of construction meet the daytime threshold limit of 65/70 dBA $L_{eq,T}$ and in many instances will be much lower than that. Since the selected instances represent the worst case for each phase of construction, it can be considered that the magnitude of change at each NSR will be Low or Very Low throughout the entire construction process. At the high sensitivity receptors (NSR4 and NSR6), the magnitude of change is always Very Low.

The magnitude of impact at each NSR, according to Table 4, is therefore found to be Minor or Negligible, and thus considered Not Significant. In no scenario does the noise impact created by the construction site meet the threshold limit set out by the BS5228 ABC method.

Estimated Noise Contours for each construction phase can be found on Figures A.2C to A.2E in Appendix A.

4.3.5 Construction Traffic Noise Assessment

The worst-case assessment of construction traffic noise at the selected points-of-reception was based on the change sound pressure levels after adding the additional construction traffic.

The total number of increased trucks per hour includes a maximum of 3 dump trucks and 4 cement/concrete trucks for a total of 7 additional heavy trucks per hour. The predicted change in noise levels at the NSRs is as follows:

Table 28 Haul Route Traffic Noise Change Due to Construction Traffic - Day

Noise Sensitive Receptor	Existing 18 hr Daytime Haul Route Traffic Noise (dBA)	Construction 18 hr Haul Route Traffic Noise (dBA)	Change Due to Construction (dBA)	Magnitude of Impact
Seymour Rd	65.4	66.3	0.9	Negligible
N Sound Rd.	71.3	72.2	0.9	Negligible
Thomas Russel Ave.	75.8	75.9	0.1	Negligible
Elgin Ave.	71.4	71.6	0.2	Negligible
Goring Ave.	71.4	71.6	0.2	Negligible
Harbour Dr.	74.0	74.1	0.1	Negligible

Table 29 Haul Route Traffic Noise Change Due to Construction Traffic – Night

Noise Sensitive Receptor	Existing 6 hr Haul Route Traffic Noise (dBA)	Construction 6 hr Haul Route Traffic Noise (dBA)	Change Due to Construction (dBA)	Magnitude of Impact
Seymour Rd	58.2	61,1	2.9	Minor
N Sound Rd.	64.1	65.7	1.6	Minor
Thomas Russel Ave.	64.8	65.7	0.9	Negligible
Elgin Ave.	60.5	62.4	2.0	Minor
Goring Ave.	60.5	62.4	2.0	Minor
Harbour Dr.	63.5	64.6	1.1	Minor

As expected, Seymour Road was the most affected road. As traffic volumes on Seymour Road are the lowest compared to all other roads along the Haul route it is expected that the change in traffic noise due to construction will be Negligible or have No Change.

5. Noise Mitigation Measures

5.1 Noise from the ISWMS Operations

As part of the safe and on-going operation of the ISWMS, best available technology will be implemented. This will help to ensure that the noise impact of the operational activities of the proposed facility on existing receptors is further reduced.

Using best available technology, specific mitigation will be applied to the operating machinery within the internal areas of the ISWMS buildings. It is understood that these mitigation measures will be put in places to comply with worker hearing protection standards. Once implemented, these measures will ensure that the noise levels within the vicinity of the operational plant buildings associated with the ISWMS will be 80dB(A) or less. This will have a positive effect on the noise impact experienced at existing sensitive receptors and can be confirmed through compliance testing at existing sensitive receptors once the facility is in full operation.

Other mitigation measures outlined in the Environmental Statement will include the implementation of best working practice to ensure that the impact of the operational activities of the proposed facilities on existing receptors is minimised. These include:

– All plant and machinery will be regularly maintained to control noise emissions, with particular emphasis on lubrication of bearings and the integrity of silencers.
– Broadband reversing alarms will be chosen instead of tonal alarms.
– Site staff will be aware that they are working in the vicinity of residential properties and avoid all unnecessary noise due to misuse of tools and equipment, unnecessary shouting and radios. Noisy external activities such as cleaning and maintenance will be scheduled to avoid night-time working in the vicinity of sensitive receptors where possible.
– All works and ancillary operations that are audible at sensitive receptors outside the Site boundary shall be carried out only during hours of 8am till 6pm.
– All equipment and machinery in use shall be properly silenced where practicable and economic and maintained in accordance with the manufacturer's instructions.
– Any emergency deviation from these conditions shall be reported to the Contractor without delay.
– All vehicles to switch off engines upon arrival at site. The Site is to be a no-idling site.
– The majority of lorry movements will be carried out in forward gear in order to minimise noise associated with vehicle manoeuvring.

Noise management objectives will be established in accordance with the Environmental Management Plan as follows:

– 65 dB(A) at a distance of one meter from existing building facades
– 75 dB (A) at the site boundaries neighbouring roads and car parks
– 80 dB (A) at all other site boundaries

In addition, once haulage routes to and from the ports are determined for both the construction and operational phases, road traffic noise monitoring will be undertaken at agreed locations along the main route(s) to and from the facilities in accordance with the shortened method within the UK's CRTN "Calculation of Road Traffic Noise".

5.2 Noise from Construction Phase Activities

To minimise the potential levels of noise generated by the construction works, best working practice would be put in place where possible. The construction works will follow the guidelines in BS5228-1 and the guidance in BRE Controlling Particles, Vapour and Noise Pollution from Construction Sites, Parts 1 to 5, 2003.

The following measures will be put in place to minimise noise emissions:

– All plant and machinery will be regularly maintained to control noise emissions, with particular emphasis on lubrication of bearings and the integrity of silencers.
– Broadband reversing alarms will be chosen instead of tonal alarms.
– Site staff will be made aware that they are working adjacent to a residential area and avoid all unnecessary noise due to misuse of tools and equipment, unnecessary shouting and radios.
– A further measure to reduce noise levels at the sensitive receptors will include, as far as possible, the avoidance of two noisy operations occurring simultaneously in close proximity to the same sensitive receptor.
– Adherence to the restriction of operating hours.
– Ensure engines are turned off when possible.

– Should construction activities need to be carried out during night-time hours, this will be discussed with the local authority, which may include a planning condition which requests advance notice and details of any night working to provided.
– The majority of lorry movements will be carried out in forward gear in order to minimise noise associated with vehicle manoeuvring.

Construction management procedures will be used to minimise noise associated with construction activity. This is likely to include the application of techniques in accordance with BS 5228: 2009 (Code of practice for noise and vibration control on construction and open sites). Such measures will where necessary include:

– Use of mufflers or silencers on tools and plant.
– Where practicable and economic, electrically powered equipment will be used in preference to diesel or gasoline, as it is quieter.
– Low noise emissions and white noise reversing alarms on vehicles that are procured for the Works Period.
– Shut down (or throttle down) of machines in intermittent use in periods between work.
– Use of acoustic fencing or stockpiles for screening sound.
– Particularly noisy activities will be limited to certain periods of the day where appropriate.
– ReGen will keep neighbours informed regarding the work that is to be undertaken on site and the associated duration.
– Prior to commencement of particularly noisy operations, an environmental procedure detailing the method of works, program of work, predicted noise levels and manufacturers specifications for equipment and machinery will be submitted to the Contractor by the Construction Sub-Contractors for acceptance.
– Where practicable noisy equipment will be located away from sensitive noise boundaries.
– Loading and unloading of vehicles, dismantling of site equipment such as scaffolding or moving equipment or materials around site will be conducted in such a manner as to reduce noise generation and where practicable will be conducted away from noise sensitive areas.
– If elevated noise / vibration levels are encountered, the source of noise or vibration is to be identified and alternative methods or additional control measures are to be implemented.
– A maximum speed limit of 5 mph (8 kph) will apply on the site for the safety of the workforce and to minimize disturbance from noise and vibration in dusty areas. During regular operations on paved roads maximum operations a maximum speed limit of 13 mph (20kph) will apply.

5.3 Residual Effects

Given compliance with the above measures, in particular the proper maintenance of equipment and of the access road surface, there will not be any significant residual impact of noise on nearby existing sensitive receptors.

5.4 Inter-Related Effects

The NSRs most susceptible to inter-related effects involving noise are NSR1 (Lakeside Residential Development) and NSR5 (Woodside Drive/Glenwood Drive Residence), as these are the receptors most affected by noise during both the construction and operational phase. Residents at these receptors may experience a slightly higher background noise level for some hours of the day during both the construction and operational phases of the ISWMS (though the adverse effects have been determined to be not significant). However, these receptors are well outside of the potential zone of influence for vibration from the facility; the local roads connecting to these residences do not lie upon the operational and haul routes for the ISWMS, so they will not be significantly impacted by traffic changes; according to the Quantitative Air Quality Assessment, air quality effects were determined to be insignificant, and odour in the area is actually expected to improve due to diversion of waste from the landfill; and view of the IWSMS from these receptors will be obscured or blocked completely by trees and other buildings. Thus, it has been judged that these

receptors will not experience any significant inter-related effects due to a combination of noise effects with other environmental impacts such as terms of vibration, traffic, air quality or visual amenity.

6. Conclusions

This NVIA describes an assessment of the potential noise impacts associated with the proposed ISWMS construction and operation.

The sound characteristics and existing ambient acoustical environment at the 4 different noise monitoring locations are characterized by road traffic noise attributed to the Esterly Tibbetts Highway, the Cayman's International Airport, local commercial/industry areas to the southeast and the natural environment. The baseline noise data collected is a good representation of typical existing sound characteristics around the ISWMS development.

GHD has measured the existing noise levels in the Study Area based on the baseline noise monitoring program described in this report. This assessment confirms that the sound levels in the Study Areas in close proximity of the Esterly Tibbetts Highway are generally high during the day and low at night, residential receptors close to commercial industries generally experience higher sound levels during the day and night, and in residential areas removed from road traffic and industry areas are generally lower, consistent with an urban area. These documented baseline sound levels were used for comparison to the predicted noise impacts during the construction and operation phases of the proposed ISWMS Project to determine the potential for noise impacts.

The potential noise impacts affecting existing sensitive receptors with regard to construction and operational activities associated with the facility have been considered, and have been assessed using appropriate guidance. A robust, ‘worst- case' scenario has been considered, with the ISWMS facility operating fully.

Where mitigation measures are required to control potential noise levels from the facility, details of such measures have been provided in outline terms.

6.1 Noise from the Proposed ISWMS Operations

Prediction calculations have been carried out to determine the noise levels likely to be generated by noise breaking out of the facility buildings, together with on-site vehicle movements, at each of the existing residential receptors. Noise levels have been predicted based on data provided by the technology providers, GHD's noise library for representative equipment and BS 5228-1.

Based on several assessments, in accordance with BS4142, it has been found that there is a potential for operational noise levels to exceed the lowest range of measured background levels during the daytime period at existing sensitive receptors located closest to the ISWMS. This is likely to be an indication of a medium/moderate magnitude of change (potentially significant) which may be an adverse impact (+5 dBA) depending on the context.

In accordance with BS4142, the context in which the sound resides must be considered as part of the assessment. As demonstrated in this assessment, when considering context, the noise impact at receptors will be significantly less and is not considered to be significant adverse due to the existing ambient environment with high existing average levels throughout the day without the ISWMS.

The impact is considered to be moderate, however with mitigation measures in place the impact is seen as low/minor in accordance with Table 7.

6.2 ISWMS Generated Road Traffic Noise

Access to the site is gained directly from the Seymour Road via the existing site access already used to route HGVs onto the local road network. It is considered that the additional HGVs will result in a negligible to minor short-term increase and a negligible long-term increase to road traffic noise levels at existing sensitive receptors. However, vehicle movements on the site have the potential to increase the ambient noise levels at existing receptors located in

the immediate vicinity of the site. These movements have therefore been considered within the operational noise assessment.

The noise from additional HGVs is considered to be negligible and have a moderate or no impact in accordance with Table 4.

6.3 Noise and Vibration from Construction Phase Activities

During the construction phase, any work carried out at the proposed development may generate noise that may propagate beyond the proposed development boundary. However, the noise generated is predicted to be within the appropriate threshold limits set out by the BS5228 standard and thus noise from construction activities has a minor or negligible impact at all sensitive receptors, in accordance with Table 4.

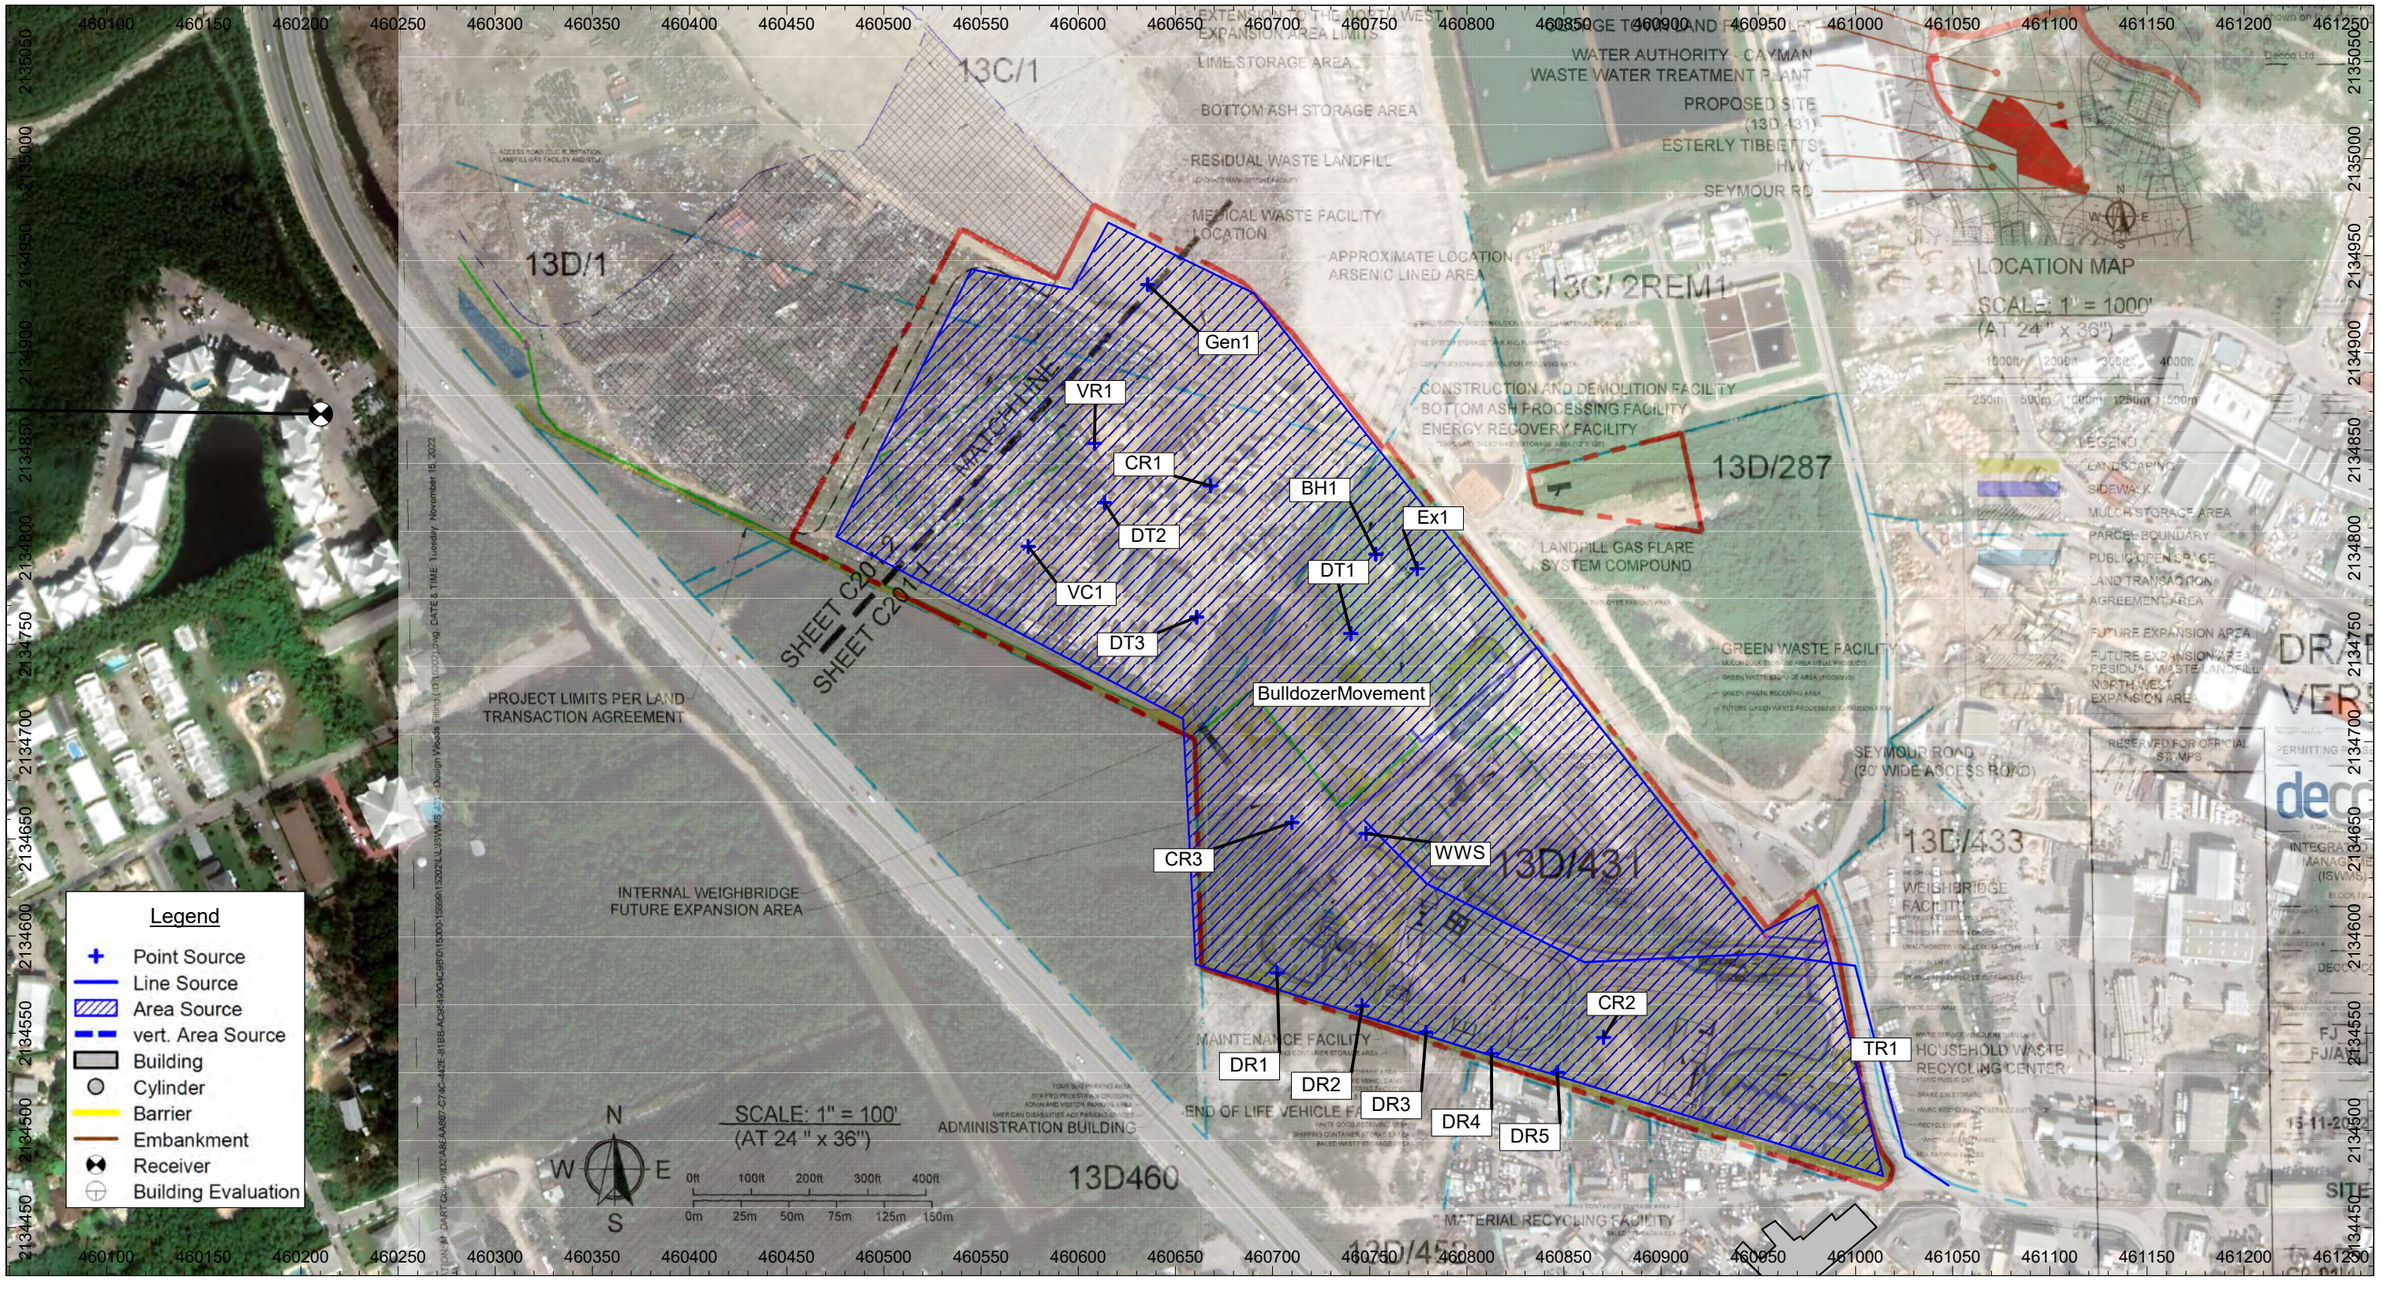
To minimise the potential levels of noise generated by the construction works, best working practice will be put in place where possible. The construction works will follow the guidelines in BS5228-1 and the guidance in BRE Controlling particles, vapour and noise pollution from construction sites, Parts 1 to 5, 2003.

GHD has deemed construction vibration insignificant for all receptors noting an EIA magnitude of change of “very low” as the vibration impacts would be <0.3 mm/s PPV below the Lowest Observed Adverse Effect Level (LOAEL).

6.4 Noise from Construction Traffic

Construction traffic along the defined Haul Route which accesses the site from Seymour Road and ends at the port will result in a minor magnitude of impact for areas along Seymour Road and a negligible magnitude of impact along the rest of the Haul route during the daytime, and a minor magnitude of impact along most roads at night. The construction traffic will therefore have a non-significant impact overall in accordance with Table 4.

6.5 Mitigation Measures



Mitigation measures have been presented within this NVIA to minimise noise emissions during construction phase activities.

During the operational phase of the development, best available technology will be used to reduce the potential impact of noise levels generated by the operational phase of the facility.

Notes:

[1] Sound Power Level (PWL) in dBA, excludes +5 dBA total penalty if applicable.
[2] Sound characteristics:
- S – Steady
- Q – Quasi-steady impulsive
- I – Impulsive
- B – Buzzing
- T – Tonal
- C – Cyclic

[3] Source location:
- O – Outside of building
- I – Inside of building

[4] Noise control measures:
- S – Silencer, acoustic louvre, muffler
- A – Acoustic lining, plenum
- B – Barrier, berm, screening
- L – Lagging
- E – Acoustic enclosure
- O – Other
- U – Uncontrolled
- AC – Administrative control

GRAND CAYMAN PROPOSED INTEGRATED SOLID WASTE MANAGEMENT SYSTEM TRAFFIC STATEMENT

1.0 INTRODUCTION

An Environmental Impact Assessment (EIA) is being undertaken for the proposed Grand Cayman Integrated Solid Waste Management System (ISWMS), commonly referred to as the ISWMS Project. The facility is part of an overall ISWMS for the entire Cayman Islands. The project is being developed by the DECCO Consortium (ReGen) in collaboration with the Cayman Islands Government (CIG). This Traffic Statement (TS) has been undertaken as part of the EIA process for the purposes of assessing the likely impacts of the ISWMS development in Grand Cayman on the surrounding road network. This report has been prepared with input from the National Roads Authority (NRA) and the Department of Environmental Health (DEH) which operates the existing George Town Landfill (GTLF) on Grand Cayman.

The proposed ReGen facilities in Grand Cayman (ReGen facilities) are mostly located on land adjacent the existing GTLF site with some of the facility utilising land previously occupied by the GTLF. The land is currently brownfield site and was previously used as part of the landfill. The site is accessed at the north end of Seymour Road in the Industrial Park area of George Town. The ReGen facilities are expected to open in 2026.

The TS is organized to set out the existing situation, present the proposed development and determine what impact, if any, the site-generated traffic will have on the surrounding road network. This report summarises the traffic study, analysis of existing and predicted future traffic flows and outlines the potential traffic and transport impacts of the facility.

A Scoping Report was prepared which outlined the proposed methodology for this traffic impact assessment. This was issued to NRA for review on October 25th, 2021. Comments were received from the NRA on December 6th, 2021 and November 16th, 2022. The Scoping Report is included in **Appendix A**. The comments from the NRA have been incorporated in the preparation of this TS report.

The Terms of Reference (ToR) for the EIA were finalised on October 7th, 2021. Section 5.8 of the ToR outlines the traffic and transport assessment that will be undertaken as part of the EIA. This document has been referenced where necessary during the preparation of this traffic impact assessment and is included in **Appendix B**.

2.0 BACKGROUND AND EXISTING CONDITIONS

The proposed ReGen facilities in Grand Cayman are located at the north end of Seymour Road (SR) in the Industrial Park area of George Town. The facilities are accessible only via SR, a cul-de-sac road off North Sound Road.

2.1 STUDY AREA

The study area for this impact assessment consists of an area stretching from the north end of Seymour Road at the entrance to the site, south along Seymour Road and encompass the intersection of Seymour Road with North Sound Road. The study area also extends east to the intersection of North Sound Road and Dorcy Drive and west to the approach to the 'Bank of Butterfield' (BOB) roundabout, where North Sound Road intersects with the Esterley Tibbetts Highway and Godfrey Nixon Way. The BOB roundabout was modelled to measure its impact on the roads within the study area.

All roads within the study area are two-way single carriageway roads. The intersection of Seymour Road and North Sound Road (NSR), and the intersection of NSR and Dorcy Drive (DD) are both unsignalised mini-roundabouts. The Bank of Butterfield (BOB) roundabout, a large two-lane roundabout exists at the western extent of the study area, where the North Sound Road intersects with the Esterley Tibbetts Highway and Godfrey Nixon Way. Refer to the **Figure 1** showing the study area and location plan.

This study will aim to quantify the impact of ReGen associated traffic on Seymour Road, North Sound Road, Dorcy Drive and BOB Roundabout.

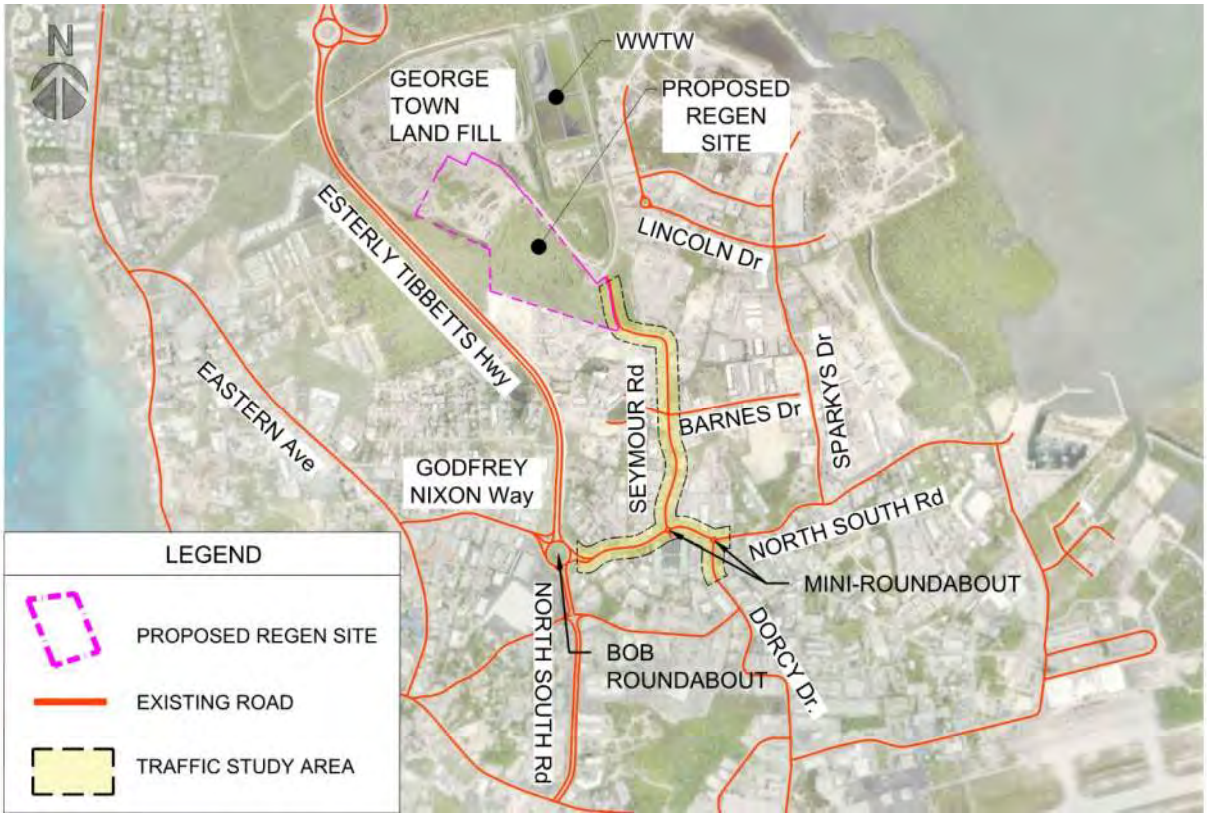

Figure 1 – Study Area location plan showing existing road network

2.1.1 PUBLIC TRANSPORT

An existing bus service exists within the study area. According to the Public Transport Unit within CIG (CaymanTransport.ky), bus 5A travels along North South Road passing the south end of Seymour Road. The frequency of the bus service is not known. There are no bus stops within the study area, however the bus service in Cayman typically stops upon request of the passengers.

2.1.2 PEDESTRIAN / BICYCLE FACILITIES

There are currently limited pedestrian facilities within the study area. There are isolated sections of sidewalks along both sides of North Sound Road. There is a limited section of sidewalk on one side of Seymour Road at a concrete batching facility.

There are no dedicated facilities for bicycles within the study area.

2.2 TRAFFIC DATA

Data of the existing traffic flows on the surrounding road network within the study area was gathered by way of a combination of automatic traffic counters[1] and turning movement counts undertaken by APEC staff. Existing traffic data was also provided by the NRA, mainly from a 2017 island-wide traffic count study.

2.2.1 EXISTING TRAFFIC VOLUMES - AUTOMATIC TRAFFIC COUNTERS

Traffic data from automatic traffic counters was collected at seven locations between December 2 and 16, 2022.

- North Sound Road (East of BOB roundabout / Agave) – 7 complete days of data (5 weekdays)
- North Sound Road (East of Tony's Toys Lot) – 7 complete days of data (4 weekdays)
- North Sound Road (Paramount / between SR & DD) – 9 complete days of data (6 weekdays)
- Dorcy Drive (Ashley furniture) – 8 complete days of data (6 weekdays)
- North Sound Road (East of Dorcy Drive intersection) – 11 complete days of data (7 weekdays)
- Seymour Road (North of intersection with NSR) – 16 complete days of data (12 weekdays)
- Seymour Road (South of GTLF entrance) – 16 complete days of data (12 weekdays)

In addition, reference has been made to traffic flow data from 2012 on Seymour Road at the GTLF entrance.

Refer to **Figure 2** for traffic count locations.

[1] PicoCount 2500 counter with pneumatic road tubes

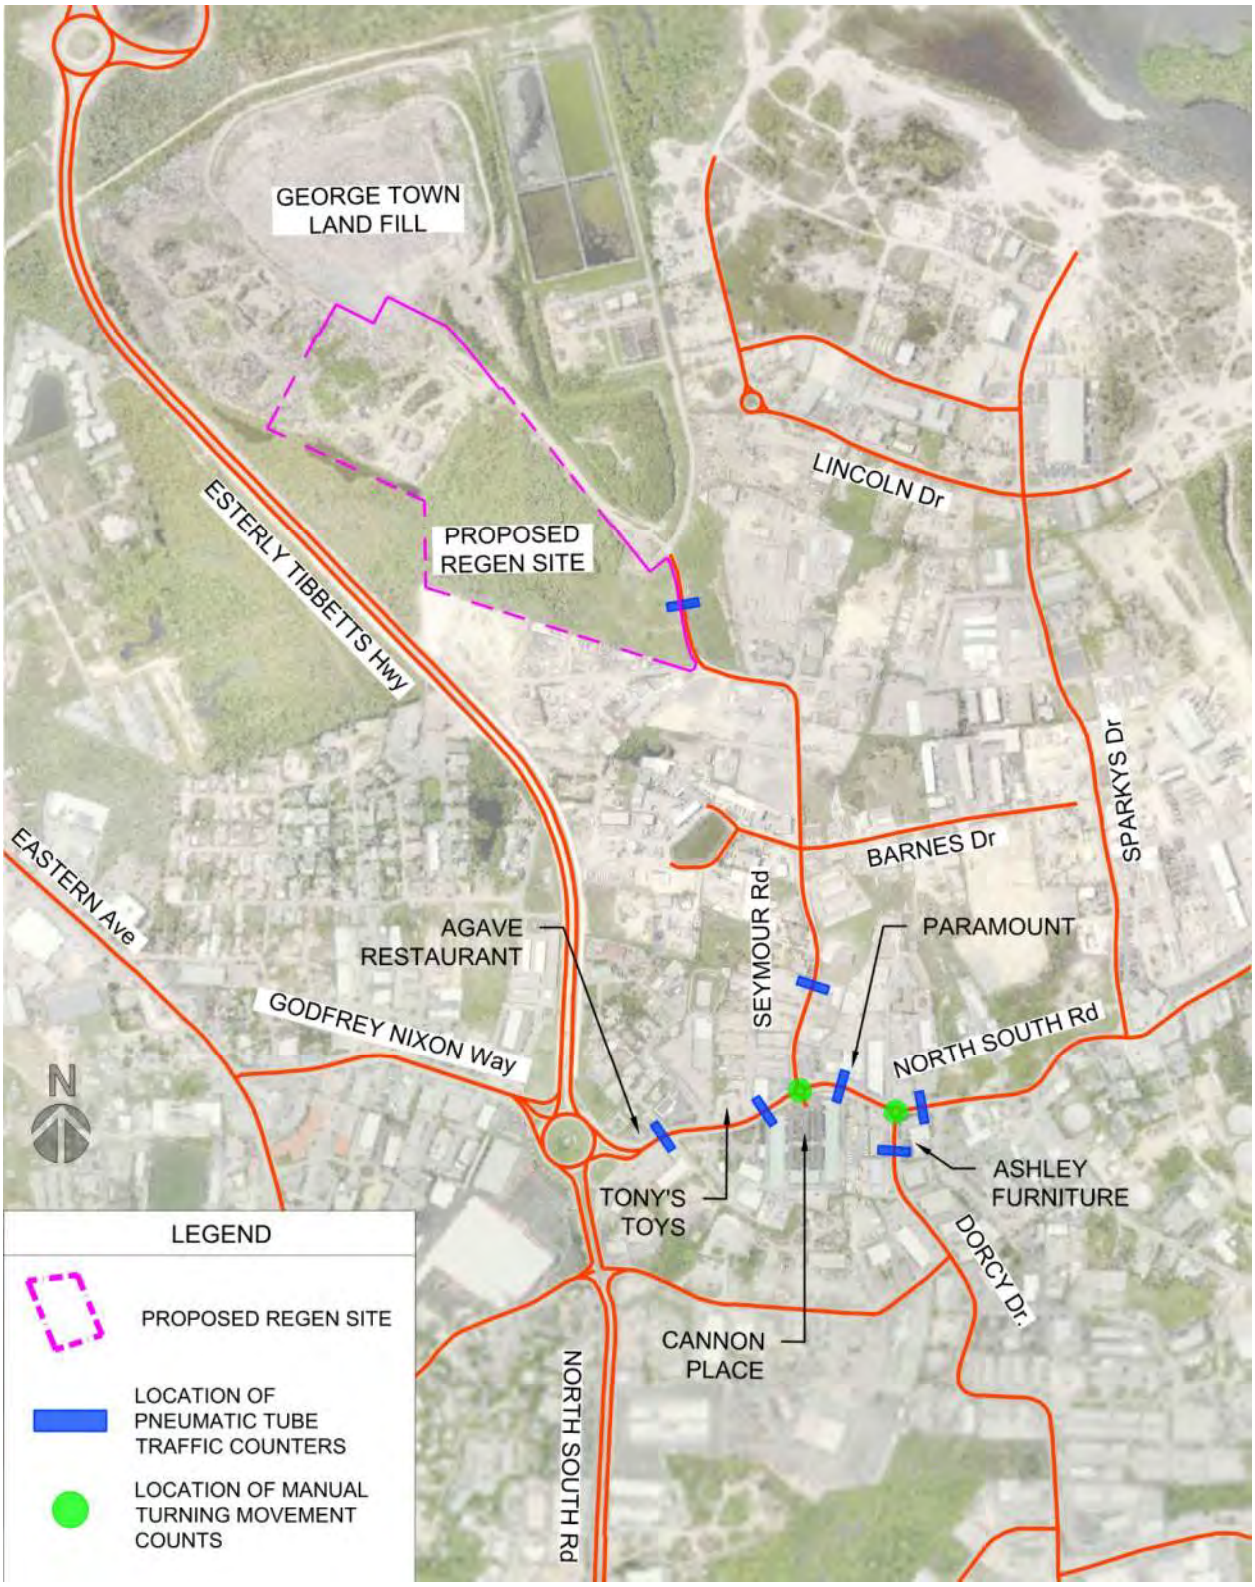

Figure 2 – Traffic Count Location Plan

The baseline traffic flow in the study area was established to assess the impact of the proposed ReGen facilities on the surrounding road network. **Table 1** through **Table 7** present a summary of the morning (AM) and afternoon / evening (PM) peak traffic flows recorded from the automatic traffic counts.

	Eastbound	Westbound	Combined
Average Weekday AM Peak 08:30 – 09:30	518	496	1014
Average Weekday PM Peak 17:45 – 18:45 [2]	373	272	645
Average Weekday ADT	5816	4654	10470

Table 1 – North Sound Road (Agave) Traffic Volume [2]

	Eastbound [2]	Westbound	Combined
Average Weekday AM Peak 09:00 – 10:00	50	511	561
Average Weekday PM Peak 18:30 – 19:30	82	439	521
Average Weekday ADT	1222	5760	6982

Table 2 – North Sound Road (East of Tony's Toys Lot) Traffic Volume [2]

	Eastbound	Westbound [2]	Combined
Average Weekday AM Peak 06:45 – 07:45	469	219	688
Average Weekday PM Peak 12:30 – 13:30	516	101	617
Average Weekday ADT	6782	2142	8924

Table 3 – North Sound Road (Paramount) Traffic Volume [2]

[2] Some traffic flow data was not recorded by the automatic traffic counters due to slow-moving nature of traffic during peak periods and the counters missing these vehicles. The automatic count data was supplemented by data from the NRA and manual turning movement counts. This may lead to slight alterations in peak traffic periods

	Northbound [2]	Southbound	Combined
Average Weekday AM Peak 07:15 – 08:15	308	284	592
Average Weekday PM Peak 18:00 – 19:00	214	226	440
Average Weekday ADT	2809	3779	6588

Table 4 – Dorcy Drive (Ashley furniture) Traffic Volume [2]

	Eastbound	Westbound	Combined
Average Weekday AM Peak 06:45 – 07:45	292	214	506
Average Weekday PM Peak 12:30 – 13:30	211	200	411
Average Weekday ADT	3006	2646	5652

Table 5 – North Sound Road (East of Dorcy Drive intersection) Traffic Volume [2]

	Northbound	Southbound	Combined
Average Weekday AM Peak 06:45 – 07:45	205	164	389
Average Weekday PM Peak 12:00 – 13:00	134	200	334
Average Weekday ADT	1908	2648	4556

Table 6 – Seymour Road (north of intersection with North Sound Road) Traffic Volume

	Northbound	Southbound	Combined
Average Weekday AM Peak 06:45 – 07:45	55	50	105
Average Weekday PM Peak 14:45 – 15:45	44	62	106
Average Weekday ADT	531	656	1187

Table 7 – Seymour Road (south of GTLF Entrance) Traffic Volume

The data from the automatic traffic counters have been included in **Appendix C**.

The data gathered from the automatic counters and provided by the NRA were used to establish the morning (AM) and afternoon / evening (PM) peak periods. These were later verified by way of manual traffic counts at intersections within the study area – refer to **Section 2.2.3**.

2.2.2 Traffic Speeds

The automatic traffic data was interrogated to calculate the average travel speed at each of the counter locations. The following table summarises the average travel speed and the posted speed limit at each counter location.

There are no visible speed limit signs within the study area. The speed limits shown were taken from The Traffic (Speed Limits in Grand Cayman) Regulations, 2016. There was no speed limit shown for Seymour Road. It has been assumed that the speed limit on Seymour Road is a continuation of the applicable speed limit on North Sound Road.

	Average Travel Speed (mph)	Posted Speed Limit (mph)
North Sound Road (East of BOB roundabout / Agave)	22.1	25
North Sound Road (East of Tony's Toys Lot)	19.1	25
North Sound Road (Paramount / between SR & DD)	19.4	25
Dorcy Drive (Ashley furniture)	19.1	25
North Sound Road (East of Dorcy Drive intersection)	20.3	25
Seymour Road (North of intersection with NSR)	16.9	25
Seymour Road (South of GTLF entrance)	18.7	25

Table 8 – Average Travel Speed & Posted Speed Limit

The data from the automatic traffic counters have been included in **Appendix C**.

2.2.3 Existing Traffic Volumes – Manual Turning Movement Counts

Manual turning movement counts were undertaken on three dates as follows:

- North Sound Road / Seymour Road mini-roundabout – December 15, 2022 (AM peak)
- North Sound Road / Seymour Road mini-roundabout – January 26, 2023 (PM peak)
- North Sound Road / Dorcy Drive mini-roundabout – March 15, 2023 (AM peak)
- North Sound Road / Dorcy Drive mini-roundabout – December 14, 2022 (PM peak)

Refer to **Figure 2** for traffic count locations.

The traffic data gathered during the manual turning movement counts is summarised in the figures below.

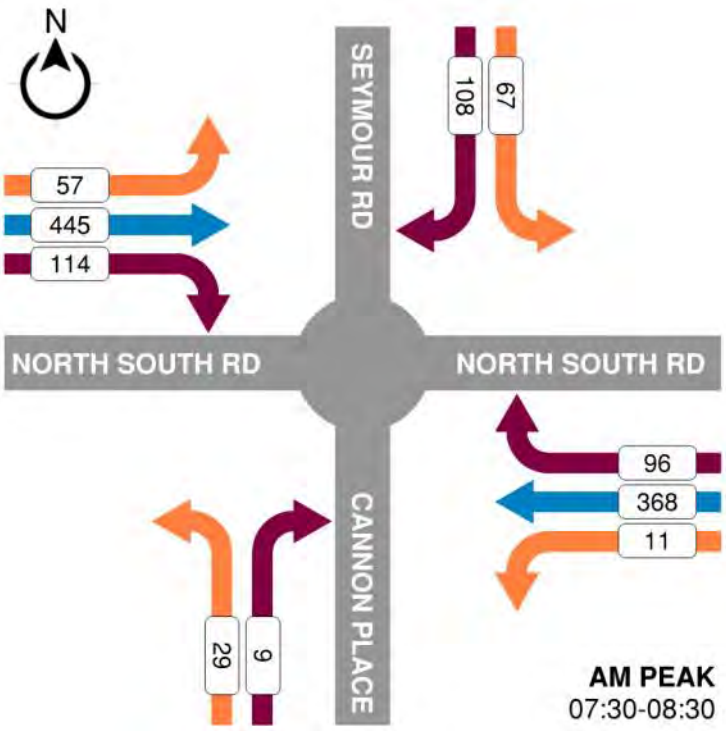

Figure 3 – Intersection of North Sound Road & Seymour Road – AM Peak

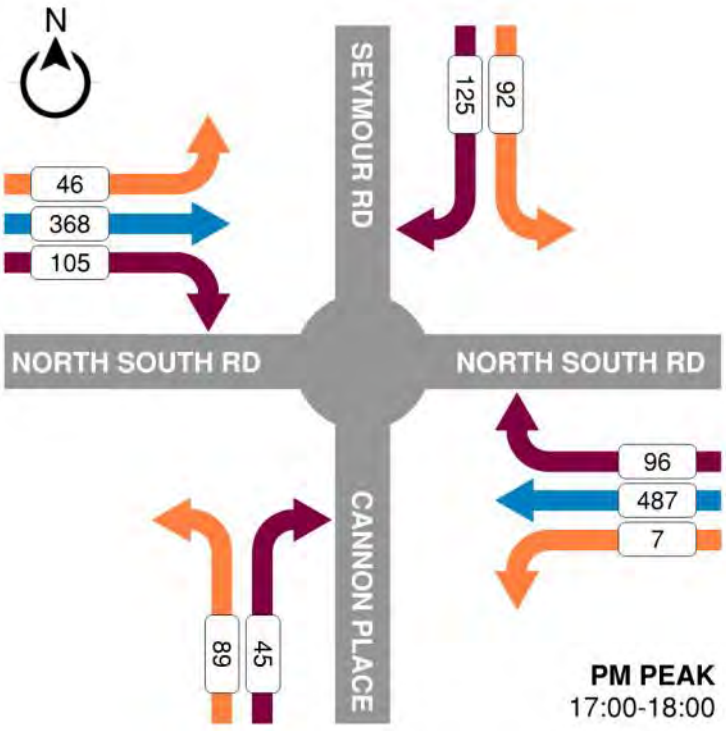

Figure 4 – Intersection of North Sound Road & Seymour Road – PM Peak

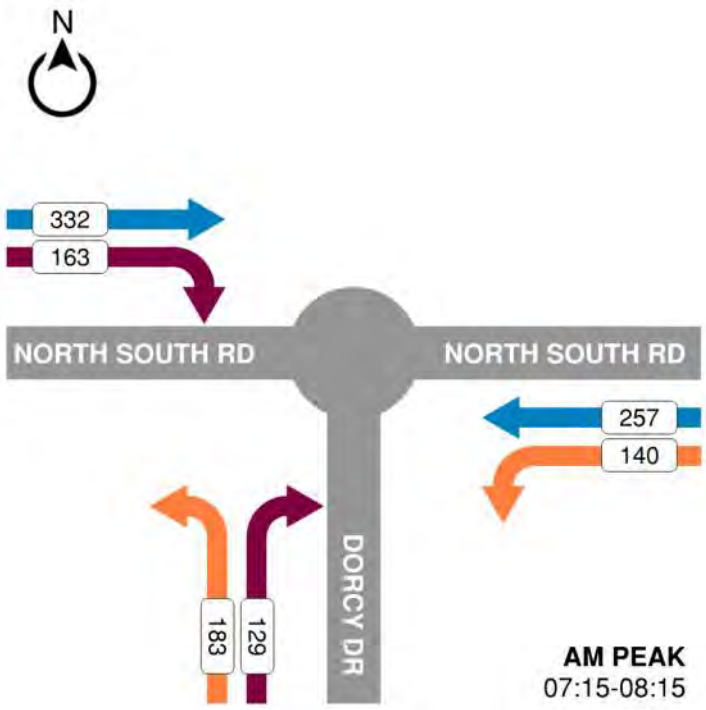

Figure 5 – Intersection of North Sound Road & Dorcy Drive – AM Peak

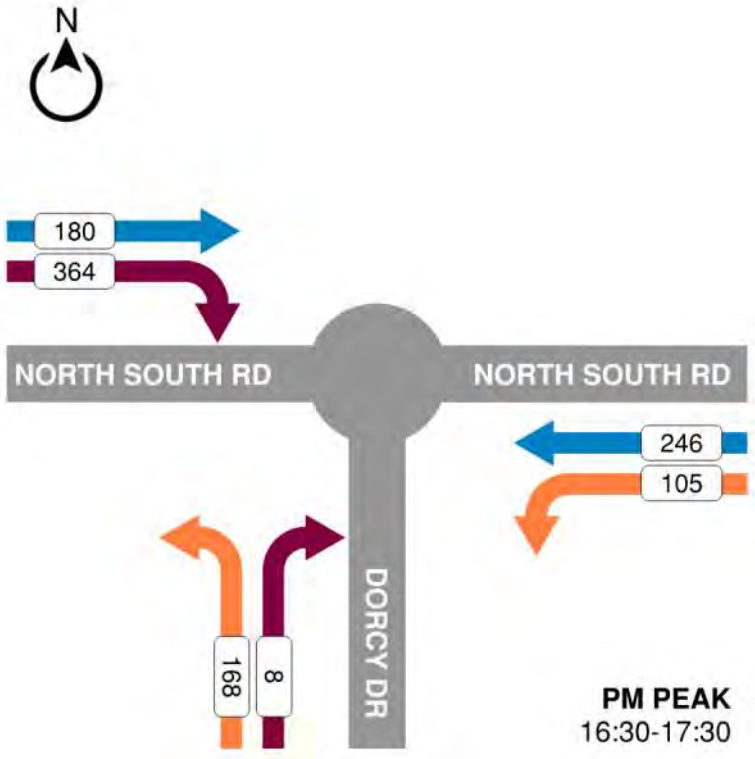

Figure 6 – Intersection of North Sound Road & Dorcy Drive – PM Peak

2.2.4 TRAFFIC CLASSIFICATION

The results from the manual traffic counts were interrogated to quantify the classification of vehicles at each of the intersection approaches. The following tables summarise the vehicle classification.

	Bicycles / Motorcycles	Cars / Pickups	Buses	Trucks / HGVs
Percentage	2%	93%	1%	4%

Table 9 – North Sound Road (West of intersection with SR) Traffic Classification

	Bicycles / Motorcycles	Cars / Pickups	Buses	Trucks / HGVs
Percentage	1%	90%	0%	9%

Table 10 – Seymour Road (at intersection with NSR) Traffic Classification

	Bicycles / Motorcycles	Cars / Pickups	Buses	Trucks / HGVs
Percentage	2%	91%	1%	6%

Table 11 – North Sound Road (between SR and DD intersections) Traffic Classification

	Bicycles / Motorcycles	Cars / Pickups	Buses	Trucks / HGVs
Percentage	1%	91%	1%	8%

Table 12 – Dorcy Drive (at intersection with NSR) Traffic Classification

	Bicycles / Motorcycles	Cars / Pickups	Buses	Trucks / HGVs
Percentage	2%	90%	1%	7%

Table 13 – North Sound Road (East of Intersection with DD) Traffic Classification

This manual traffic count data is included in **Appendix D**.

The results from the automatic traffic counter located south of the entrance to the GTLF were interrogated to quantify the classification of vehicles. The following table summarise the vehicle classification.

	Bicycles / Motorcycles	Cars / Pickups	Buses	Trucks / HGVs
Percentage	2%	76%	1%	21%

Table 14 – Seymour Road (South of GTLF entrance) Traffic Classification

2.2.5 EXISTING TRAFFIC VOLUMES – NRA TRAFFIC COUNTS

Existing traffic flow data has been received from the NRA[3] for the following locations in and around the study area:

- North Sound Road (South of Godfrey Nixon Way) – 2019
- Esterley Tibbetts Highway (by Lakeside Development) - 2019
- Godfrey Nixon Way (east of Eastern Avenue) – 2019
- North Sound Road (Tony's Toys Lot) – 2017
- Dorcy Drive (south of Ashley furniture) – 2017
- North Sound Road (East of Dorcy Drive intersection) – 2017
- Intersection Turning Movement Count for Bank of Butterfield roundabout - 2016
- Intersection Turning Movement Count for North Sound Road / Dorcy Drive - 2016

The turning movement count data for Bank of Butterfield roundabout have been included in **Appendix E**.

Traffic data from the 2016 turning movement count at Bank of Butterfield roundabout were used to establish peak period traffic flows through the intersection. The data from 2016 were increased in line with NRA established growth rates (see **Section 4.2**) to provide 'base year', 2022, traffic flows. The classification of vehicles utilising the roundabout intersection was taken from the data provided by the 2016 count. Refer to **Figure 7** and **Figure 8** summarising the calculated AM and PM peak flow data for the 2022 Base Year.

[3] Additional traffic data was received from the NRA but was deemed not relevant for this traffic study

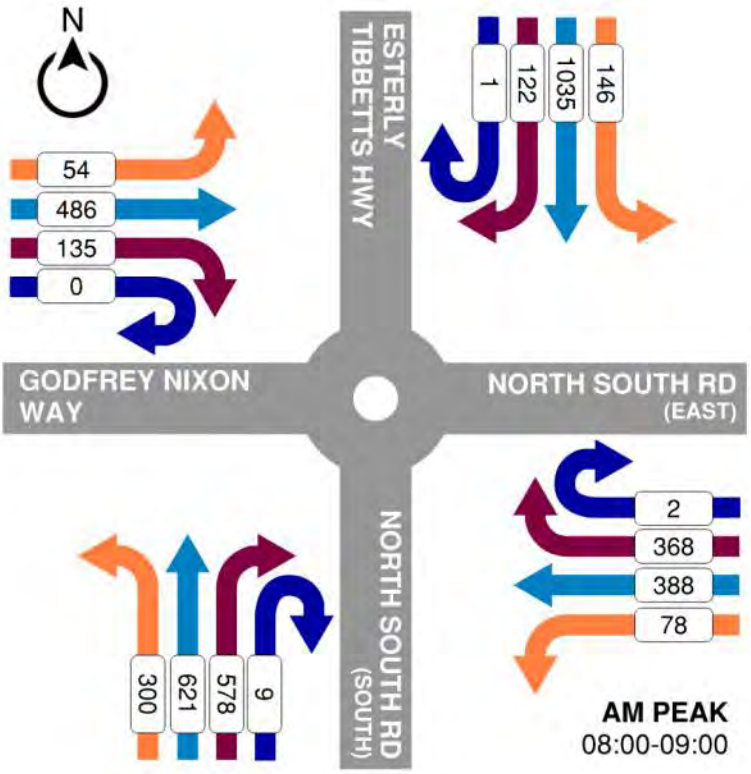

Figure 7 – Bank of Butterfield roundabout – AM Peak

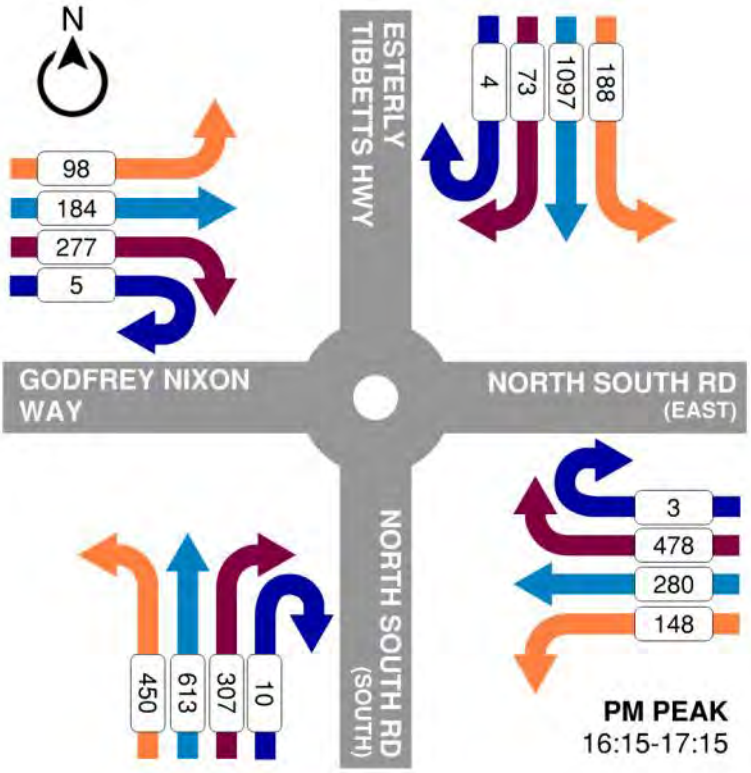

Figure 8 – Bank of Butterfield roundabout – PM Peak

2.2.6 EXISTING / BASE YEAR PEAK HOUR TRAFFIC FLOW ANALYSIS

Analysis has been undertaken of the existing traffic flows within the study area to establish the current Level of Service (LOS) on the surrounding roads. This analysis is based on several available data sets:

- Turning Movement Count data for 'Bank of Butterfield' roundabout made available by the NRA - 2016
- Manual Traffic Count undertaken at North Sound Road / Seymour Road mini-roundabout - 2022
- Manual Traffic Count undertaken at North Sound Road / Dorcy Drive mini-roundabout - 2022

Interrogation of the available data has established the traffic flows on the surrounding road network during both the morning (AM) and afternoon / evening (PM) peak hours. While the peak periods of each intersection do not necessarily match, the worst-case peak has been used to provide a robust analysis. The vehicle classification information from the available data was used to apportion heavy goods vehicles (HGVs), buses, bicycle / motorcycles, and passenger cars on the road network within the analysis models. The focus of this analysis review will be on roads within the study area.

Level of service (LOS) is a term used to qualitatively describe the operating conditions of a roadway based on measures related to speed and travel time, freedom to manoeuvre, traffic interruptions, and comfort and convenience. The LOS ranges from A (least congested) to F (most congested). **Table 14** shows the definitions of each level of service.

Level of Service	General Operating Conditions
A	Free flow
B	Reasonably free flow
C	Stable flow
D	Approaching unstable flow
E	Unstable flow
F	Forced or breakdown flow

Table 14 - General Definitions of Levels of Service

Based on previous discussions with the NRA, the minimum LOS standard for roads within the Cayman Islands is LOS "D". Any step below LOS "D" would require mitigation action to improve the traffic flow.

The traffic flow data was analysed using Sidra Intersection[4], version 7 using Highway Capacity Manual 2010 capacity calculations. The three main intersections on the surrounding road network were analysed individually and as well as part of the overall North Sound Road network. Refer to **Figure 9** through **Figure**

[4] Sidra Intersection is a software package used for intersection and network capacity, level of service and performance analysis, and signalised intersection and network timing calculations by traffic design, operations, and planning professionals.

16 showing the resulting Level of Service for each approach / lane of each intersection during both the AM and PM peak hours.

The LOS is colour-coded on the following diagrams as follows:

LOS A LOS B LOS C LOS D LOS E LOS F

The approach / lane LOS for the BOB roundabout during the AM peak is shown in **Figure 9**. The results show that the North Sound Road (East) approach, as well as other approaches, experience LOS F during the AM peak period. Additional results from the Sidra analysis show that the 95% percentile queue length on the North Sound Road (East) approach is 154 vehicles, equating to an estimated distance of 0.7 miles. The analysis shows that this intersection is currently operating above capacity during the AM peak period.

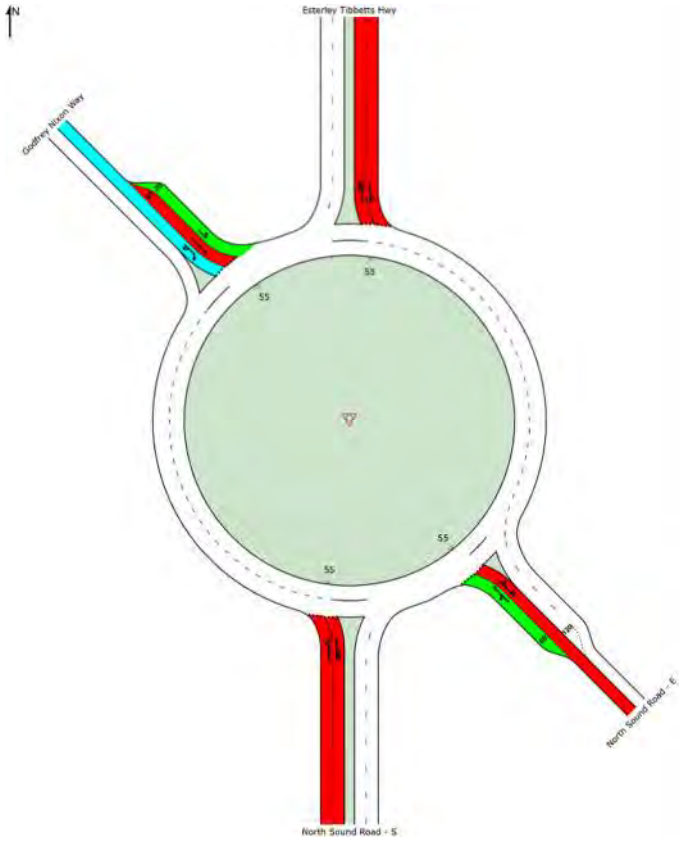

Figure 9 - Sidra Model – Bank of Butterfield roundabout - 2022 - AM Peak - Lane LOS

The approach / lane LOS for the BOB roundabout during the PM peak is shown in **Figure 10**. The results show that the North Sound Road (East) approach, as well as other approaches, experience LOS F during the PM peak period. Additional results from the Sidra analysis show that the 95% percentile queue length on the North Sound Road (East) approach is 375 vehicles, equating to an estimated distance of nearly 1.7 miles – longer than the entire length of North Sound Road therefore shows that the queue extends onto other roads upstream. The analysis shows that this intersection is currently operating beyond capacity during the PM peak period.

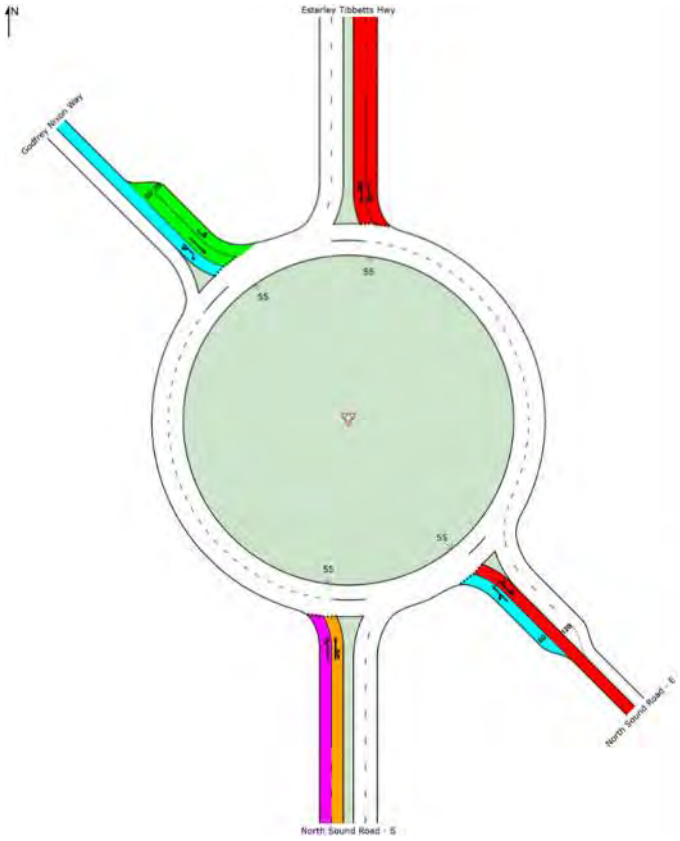

Figure 10 - Sidra Model – Bank of Butterfield roundabout - 2022 - PM Peak - Lane LOS

The approach / lane LOS for the North Sound Road / Seymour Road mini-roundabout during the AM peak is shown in **Figure 11.** The results indicate that all roundabout approaches operate at LOS A during the AM peak period.

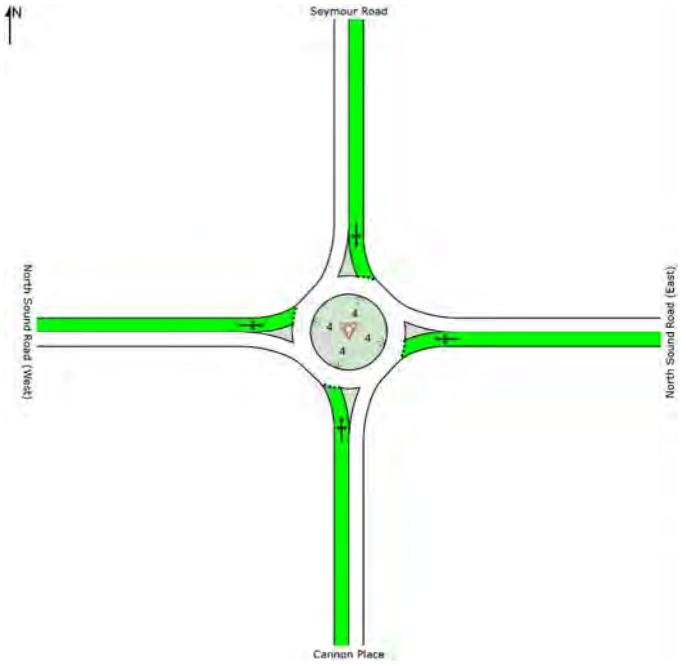

Figure 11 - Sidra Model – Seymour Road roundabout - 2022 - AM Peak - Lane LOS

The approach / lane LOS for the North Sound Road / Seymour Road mini-roundabout during the PM peak is shown in **Figure 12.** The results show that the Seymour Road approach experiences LOS B, with the remaining approaches operating at LOS A during the PM peak period.

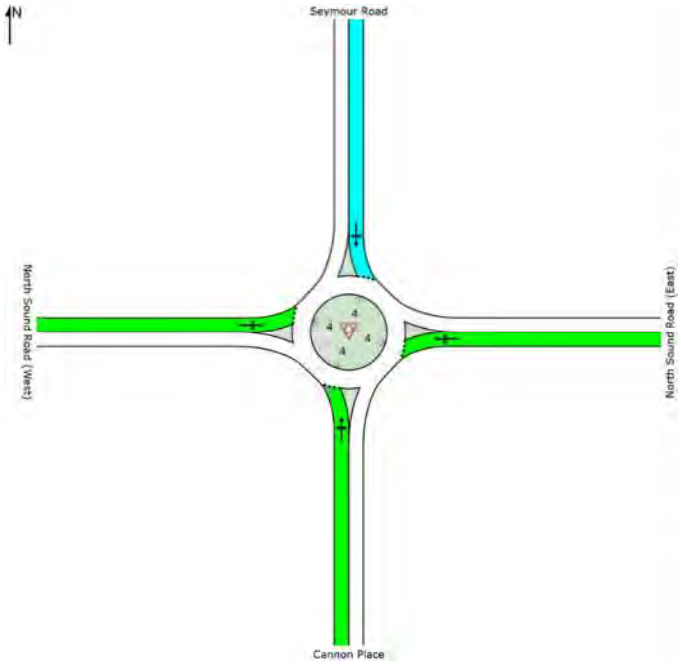

Figure 12 - Sidra Model – Seymour Road roundabout - 2022 - PM Peak - Lane LOS

The approach / lane LOS for the North Sound Road / Dorcy Drive mini-roundabout during the AM peak is shown in **Figure 13**. The results show that all approaches operate at LOS A during the AM peak period.

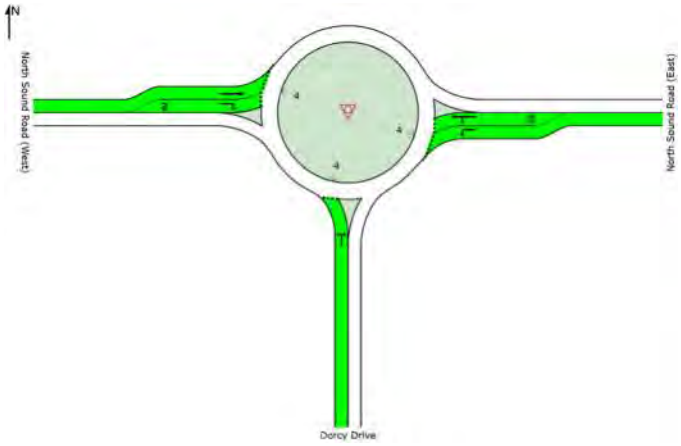

Figure 13 - Sidra Model – Dorcy Drive roundabout - 2022 - AM Peak - Lane LOS

The approach / lane LOS for the North Sound Road / Dorcy Drive mini-roundabout during the PM peak is shown in **Figure 14**. The results show that all approaches also operate at LOS A during the PM peak period.

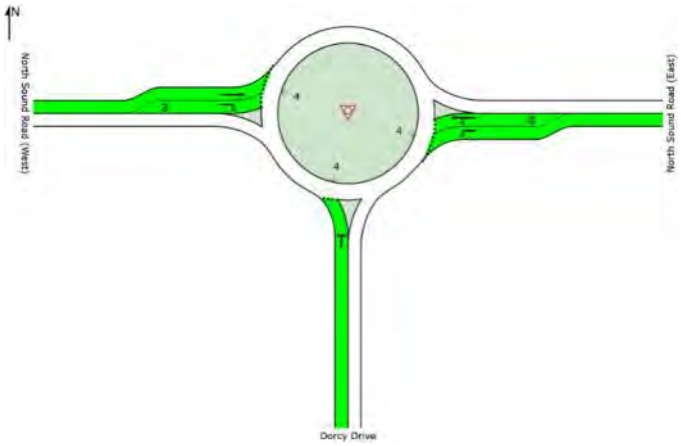

Figure 14 - Sidra Model – Dorcy Drive roundabout - 2022 - PM Peak - Lane LOS

The analysis of the surrounding road network as a whole, which includes the three intersections above, shows that much of the network is affected by the BOB roundabout. During the AM peak the queue length (circa 0.7 miles) on the North Sound Road (East) approach to the BOB roundabout affects the upstream intersections as can be seen in **Figure 15**. The queue length results in a LOS F for the section of North Sound Road between BOB roundabout and Seymour Road, and LOS B for a section of North Sound Road east of Seymour Road.

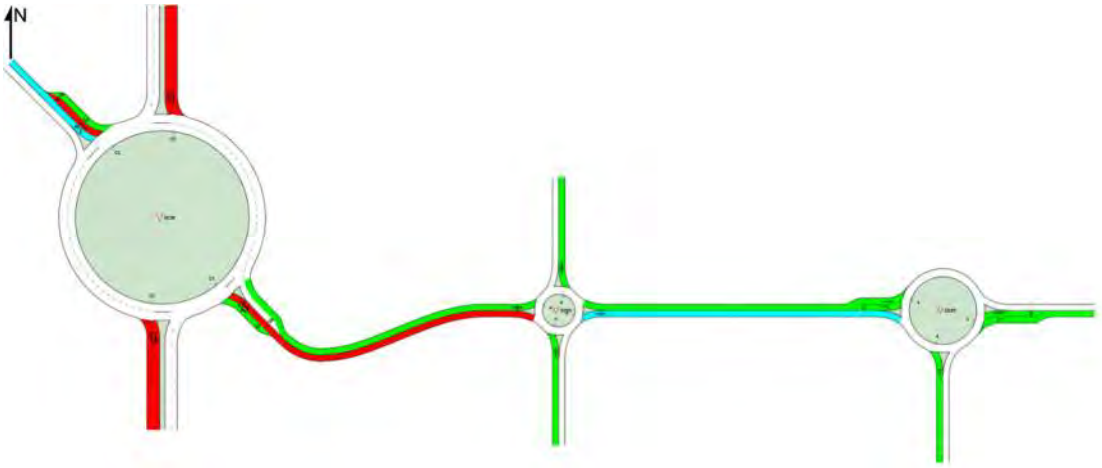

Figure 15 – Sidra Model - North Sound Road Network - 2022 - AM Peak - Lane LOS

The analysis of the surrounding road network also shows that much of the network is affected by the BOB roundabout during the PM peak period. The queue length (circa 1.7 miles) on the North Sound Road (East) approach to the BOB roundabout affects the upstream intersections as can be seen in **Figure 16**. The queue length results in a LOS F on North Sound Road. Further, empirical evidence would suggest that this queue and resulting capacity issues are experienced further upstream on North Sound Road and on side roads – Seymour Road and Dorcy Drive.

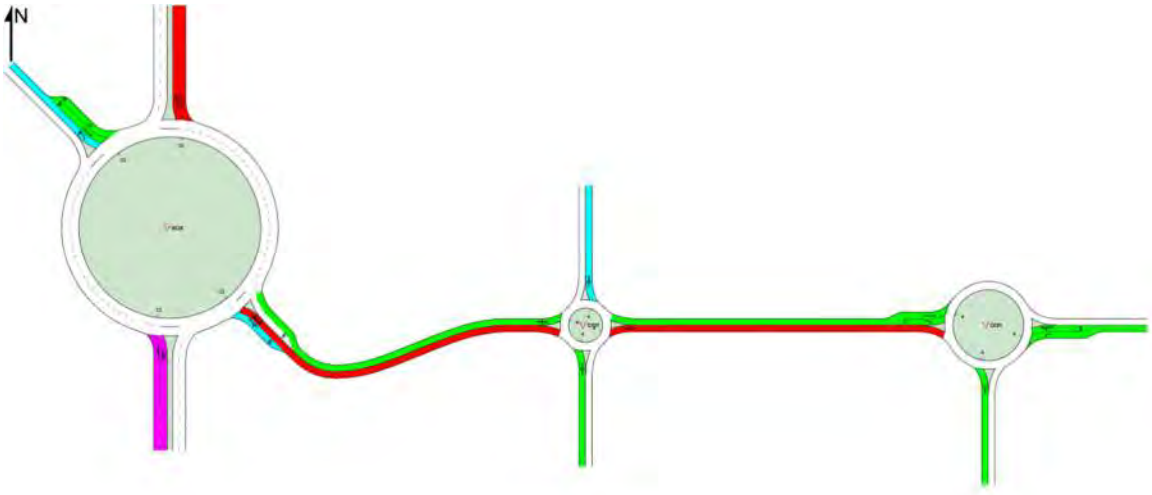

Figure 16 – Sidra Model - North Sound Road Network - 2022 - PM Peak - Lane LOS

2.3 OPERATION OF EXISTING GTLF FACILITY

In order to estimate the volume of vehicles accessing the proposed ReGen facilities, it is necessary to undertake some analysis of the current operation and usage of the GTLF. There are two main types of waste generator that use the existing GTLF, namely civic amenity drop-offs by the public, and waste collection provided by the DEH Waste Collection Service (WCS) or private waste haulers.

The civic amenity drop-off area is for use by the general public with any light / medium vehicles such as a car, pickup or van. The public can dispose of any form of waste including household, vegetation, construction, metal, etc. in large skips located adjacent to the entrance to the landfill. Once filled, these skips are transported to and disposed of in the main landfill area. Household hazardous waste, car batteries etc. are collected separately and stored at the GTLF for later transportation overseas.

The posted operational hours for acceptance of bulk waste are 07:00 to 18:30 Monday to Saturday. The civic amenity drop-off area is open 24 hours, seven days per week. DEH has previously noted that, on infrequent occasions, the GTLF landfill is opened on Sundays for bulk waste when special demolition projects are underway that require access to the landfill.

The automatic traffic count undertaken in December 2022 gathered traffic flow data on Seymour Road just south of the existing entrance to the GTLF. **Table 7** on page **7** summarises the traffic flow along that section of Seymour Road. The data shows that on average 50 - 60 vehicles arrive and depart the GTLF during the AM and PM peak periods. The traffic data from 2012, reinforced with the data from 2022 shows that the peak traffic flows associated with the GTLF occur mostly outside the peak traffic periods of the surrounding intersections / roads.

3.0 PROPOSED DEVELOPMENT

The proposed ReGen facilities comprise a multi-element development, including an energy recovery facility (ERF) and supporting non-ERF waste processing, treatment, and disposal facilities. Additional features of the ISWMS facilities include a green waste and mulching / composting facility, a household waste recycling centre (HWRC), a Materials Recycling Facility (MRF), a construction & demolition (C&D) waste processing facility, an end-of-life vehicle (ELV) and scrap metal processing facility, a landfill gas facility, a residual waste landfill (RWL) and administration & maintenance facilities. The ReGen facilities are expected to open in **2026**.

The ReGen facilities are located on land occupied by the GTLF and adjacent lands, some of which were previously used for landfill purposes. Refer to **Figure 17** showing the proposed site layout of the facility.

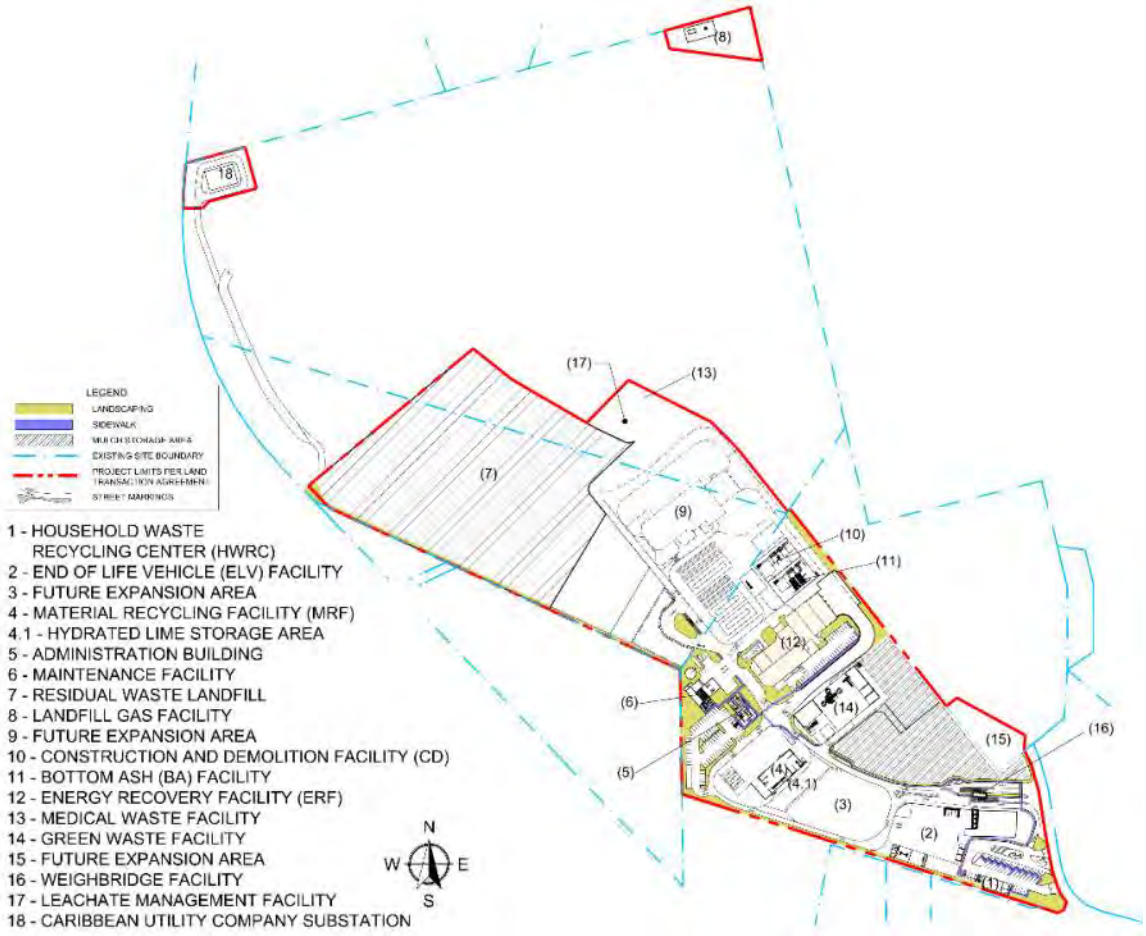

Figure 17 - Proposed Integrated Solid Waste Management Facility Layout

The proposed working hours for the ReGen facilities will vary based on the specific work demands and needs, as well as differing hours for both the public and companies using the facilities. The hours have not been finalised, however - the following information was included in the ToR for the EIA and / or has been advised by the facilities design team:

- ERF – the ERF will be functioning 24/7 (except for of approx. 10 days of planned annual maintenance) with opening hours from 04:00 - 18:00 Monday to Friday, 06:00-16:00 Saturday and Bank Holidays, and closed Sunday, Good Friday & Christmas Day
- MRF, C&D, ELV, RWL and Green Waste Facilities – will generally operate normal business hours
- Medical Waste Facility – will be open for 2 days per week, as required
- HWRC – will be open to the public for 52 hrs per week but the hours will include weekends

According to the ToR for the EIA and based on discussions with the facilities design team, there are expected to be some 70 full-time staff working on the ReGen site. This is comparable to the exsiting staffing levels at the GTLF, which is currently at 99. Staff parking, including disabled parking, will be provided on site. The site layout has been designed to allow free flow of vehicles that access both the public and back-of-house areas. Vehicle swept path movements have been tested using Autodesk's Vehicle Tracking software to ensure that sufficient space has been provided for turning manoeuvres. Pedestrian sidewalks will be provided throughout much of the site to ensure safe access for staff and patrons. There are no plans currently to modify or augment the current public transport provisions within the study area.

As per of the overall ISWMS proposal, the waste management procedures for the sister islands (Cayman Brac and Little Cayman) will change. It is proposed that waste will be collected and bulked in Cayman Brac before shipping to Grand Cayman for treatment at the ReGen facilities. As a worst-case estimate, it is expected that shipments will occur weekly with up to 10 truck movements per shipment to transport the waste from the port in George Town to the ReGen site at the opening year and up to 19 truck movements forecast by 2050. .

4.0 FUTURE CONDITIONS

4.1 TRIP GENERATION / ATTRACTION

In order to assess the impact of the ReGen facilities on the surrounding road network, it is first necessary to estimate the likely facility trip generation during the peak hour. The proposed ReGen public / private agreement will not alter how waste is collected on Grand Cayman. It will arrive at the expanded facility in the same manner as currently managed. It is therefore assumed that the trips generated by the ReGen facilities will be similar to the trips currently generated by the GTLF.

4.2 ASSESSMENT YEAR HORIZONS

As part of the impact assessment of the proposed ReGen facilities, the analysis has identified three assessment year horizons in order to fully evaluate the potential impacts. These horizons are the Opening Year of the facility, the Near-Term Year (5 years after opening) and Medium-Term Year (10 years after opening). It is expected that the Opening Year of the facility will be **2026**, therefore giving a Near-Term assessment year of **2031** and Medium-Term Year assessment of **2036**. The Base Year for traffic flow is **2022**, the year traffic data was predominately gathered.

In addition to the ReGen related trips, other factors combine to generate future traffic flows. These include background traffic increases based on population growth and increased car ownership. The NRA developed a Travel Demand Model (TDM) following their island-wide traffic study in 2017. Based on this model and the anticipated population growth on island, the NRA predicts annual growth in traffic flow to be 4% on arterial roads such as the Esterley Tibbetts Highway and the 4 lane North Sound Road continuing south, and 2% on other roads. Based on this, the traffic flows on the surrounding arterial and other road network can be expected to increase from the Base Year by the growth rates outlined in **Table 15**. It is anticipated that waste generation and the traffic flows on Seymour Road associated with the ReGen facilities will increase in a similar manner to those outlined above, at 2% per annum.

Based on a comparison of the recent traffic count data with data from a 2012 traffic count on Seymour Road (at the GTLF entrance), it has been noted that traffic flows to / from the GTLF have increased at an average rate of 3.6% per annum for the past 10 years. This is likely due to an increase in waste generation from ongoing development and population increase. In order to provide a robust analysis it has been assumed that the traffic associated with landfill facility will continue to grow at 4% per annum. It has also been assumed that the staff levels will remain the same and not reduce as preliminary staffing estimates suggest.

The forecast increase in traffic flow at the GTLF entrance (due to 4% growth in landfill related traffic and the additional staff) approximately equates to a 3% growth rate on the Seymour Road traffic at the NSR / SR roundabout - a 3% growth rate has therefore been employed locally on the associated approaches to this intersection. Refer to **Table 15** for the forecast growth for the assessment years and **Table 16** for the HGV forecast growth

Assessment Year Horizon	Growth Rate		
	Arterial Roads (4% per annum)	Other Roads (2% per annum)	Seymour Road (3% per annum)
Opening Year 2026	17%	8%	13%
Near-Term 2031	42%	20%	30%
Medium-Term Year 2036	73%	32%	51%

Table 15 – Assessment Year Growth Rates

Assessment Year Horizon	Grand Cayman Traffic (4% per annum)	Sister Island Trans-shipment	ReGen Traffic (HGV Classification)
Base Year 2022	-	-	21%
Opening Year 2026	17%	10	22%
Near-Term 2031	42%	12	22%
Medium-Term Year 2036	73%	14	22%

Table 16 – Assessment Year GTLF HGV Classification

4.3 Trip Distribution

It is expected that traffic accessing the ReGen facilities will travel to the site in a similar manner as they currently access the GTLF site. Waste collections will not alter significantly from the current arrangement. For this reason, it is assumed that trip distribution on the surrounding road network will be in line with current distribution of traffic associated with the GTLF.

4.4 Proposed Road Developments in Study Area

The Airport Connector Road is a new two-way median divided road that will connect the Esterley Tibbetts Highway (south of Camana Bay) to the north end of Sparky Drive. The road will travel adjacent the northern boundary of the ReGen facilities, however no access will be available to the site from the road. Part of this road is currently under construction. The expected completion date of this road is not known. It is expected that this road will divert a significant proportion of the traffic to the airport and eastern parts of the Industrial Area that is currently traveling along North Sound Road. An assessment of any rearrangement of traffic distribution is outside the scope of this report.

This TS does not include an assessment of future developments within the study area other than the ReGen facilities. It is assumed that any such development will be subject to separate assessment and permitting

process, however it is assumed that traffic flow from any such development will be in line with background growth as outlined above.

4.5 FUTURE TRAFFIC DATA

The following section presents the predicted traffic flows within the study area and adjacent intersection for the three assessment years outlined above. The traffic flows have been calculated using the traffic data presented in **Sections 2.2.3** and **0** and the growth rates identified in **Table 15**.

Traffic impact assessments such as this would typically measure impacts of a proposed development based on two scenarios – with and without development. These scenarios draw traffic flow comparisons between the scenario where the development is realised and a scenario where the development does not proceed. In the case of the proposed ReGen facilities, the with and without development scenarios are the same. This is due to the prediction that traffic flows generated by the ReGen facilities are expected to be similar as those generated by the GTLF site. For this reason, the future traffic flows presented here are confined to the horizon years outlined above, based on the predicted growth in traffic flows on surrounding road network.

4.5.1 OPENING YEAR – 2026

The following figures summarise the predicted peak hour traffic flows on intersections within the study area during the Opening Year, 2026.

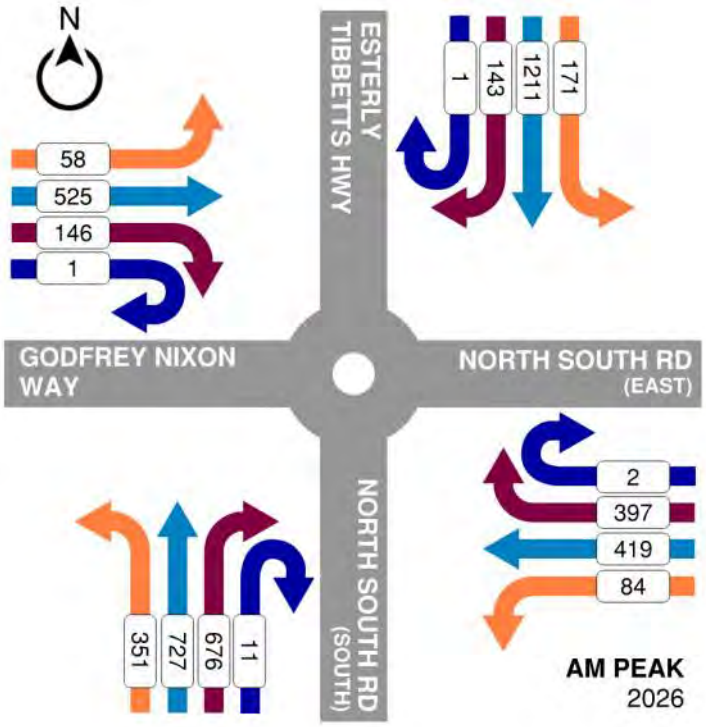

Figure 18 – Bank of Butterfield roundabout – AM Peak – 2026

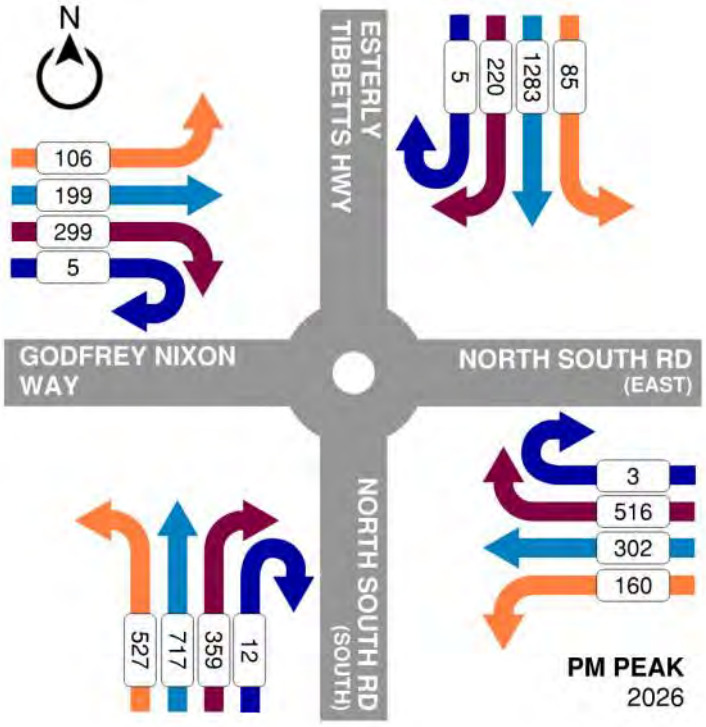

Figure 19 – Bank of Butterfield roundabout – PM Peak - 2026

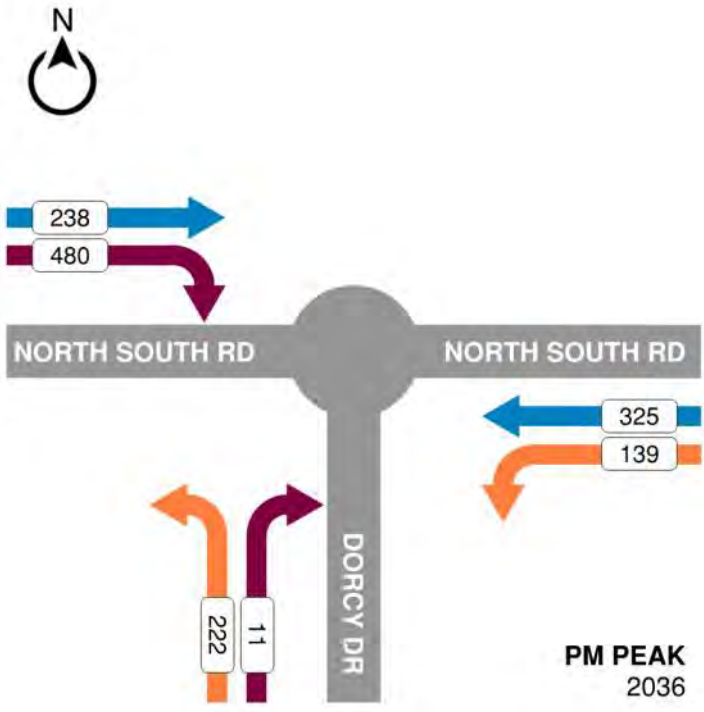

Figure 35 – Intersection of North Sound Road & Dorcy Drive – PM Peak - 2036

4.6 TRAFFIC ANALYSIS

Analysis of the predicted future traffic flows on the surrounding network has been undertaken. As outlined above, the predicted future traffic flows are due to background growth on the network and are not directly related to the development of the ReGen facilities – they are predicted to occur whether the ReGen facilities are constructed or not.

Traffic analysis has been undertaken for the three Assessment Horizons – Opening Year (2026), Near-Term Year (2031) and the Medium-Term Year (2036). The traffic flow data was analysed using Sidra Intersection software, as it was for the Base Year Peak Hour Traffic Flow Analysis in **Section 2.2.6**. Findings are presented based on the analysis undertaken.

A reminder that the LOS is colour-coded on the following diagrams as follows:

LOS A LOS B LOS C LOS D LOS E LOS F

4.6.1 OPENING YEAR ASSESSMENT HORIZON - 2026

The three main intersections on the surrounding road network were analysed individually and as well as part of the overall North Sound Road network. Refer to **Figure 36** through **Figure 43** showing the predicted Level of Service for each approach / lane to each intersection for the 2026 Near-Term assessment horizon.

The approach / lane LOS for BOB roundabout during the AM and PM peaks are shown in **Figure 36** and **Figure 37**, respectively. The results show that most approaches to the intersection will continue to experience significant capacity issues due to background traffic growth. In particular, the northbound approach for North Sound Road (South) degrades from LOS D & E in 2022 to LOS F in 2026.

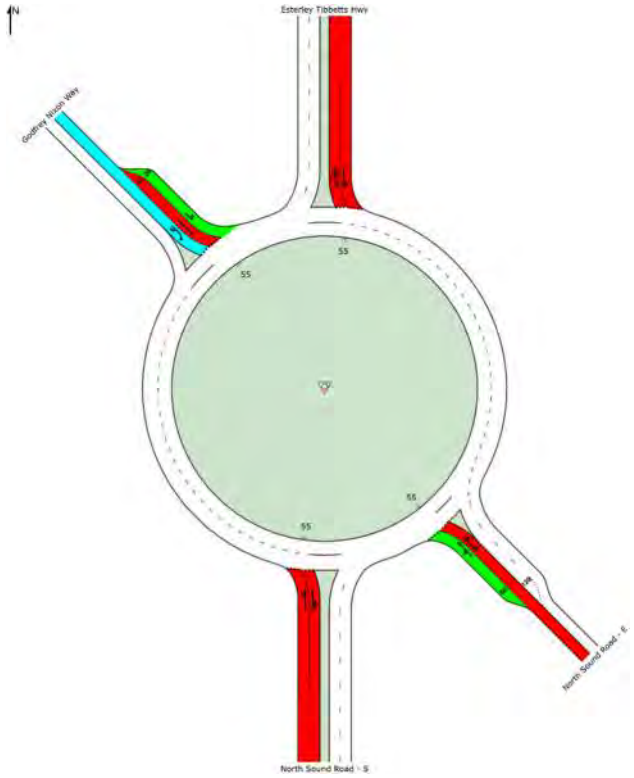

Figure 36 - Sidra Model – Bank of Butterfield roundabout - 2026 - AM Peak - Lane LOS

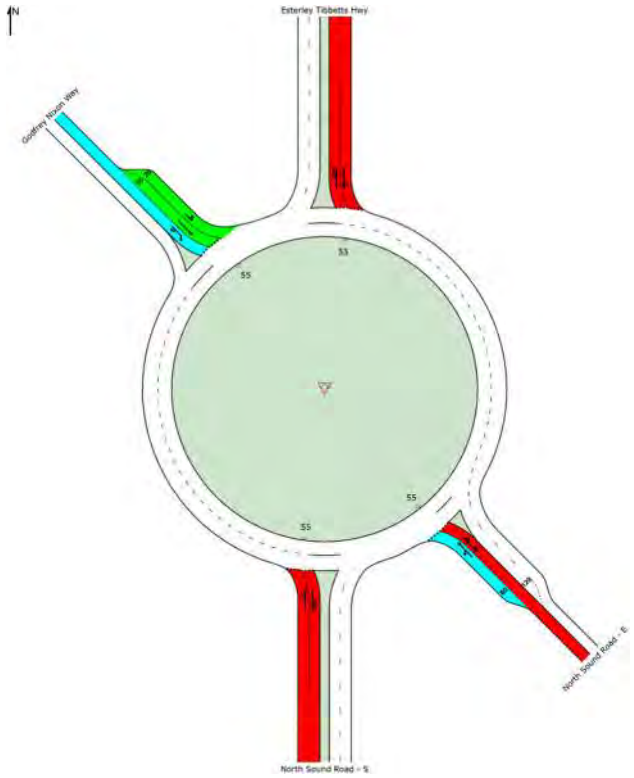

Figure 37 - Sidra Model – Bank of Butterfield roundabout - 2026 - PM Peak - Lane LOS

The approach / lane LOS for the North Sound Road / Seymour Road mini-roundabout during the AM and PM peaks are shown in **Figure 38** and **Figure 39.** The results show that the Seymour Road and North Sound Road (East) approaches are predicted to degrade in the peak periods in the coming years.

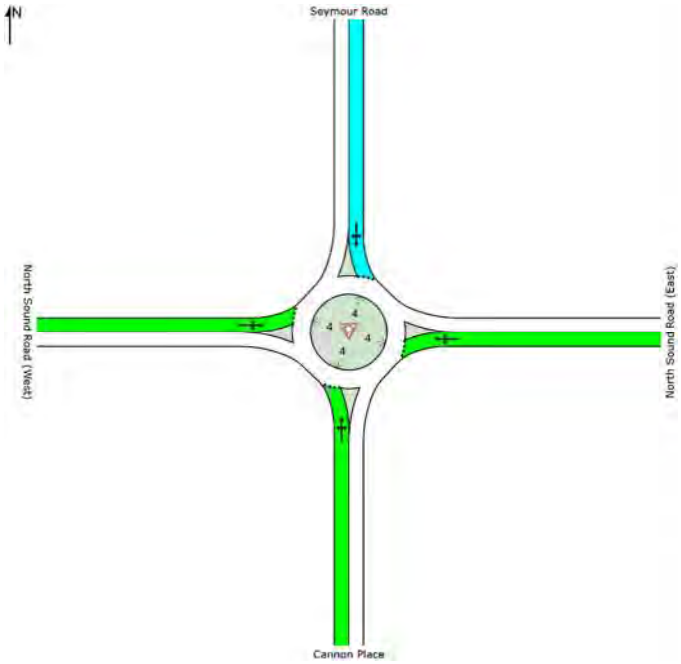

Figure 38 - Sidra Model – Seymour Road roundabout - 2026 - AM Peak - Lane LOS

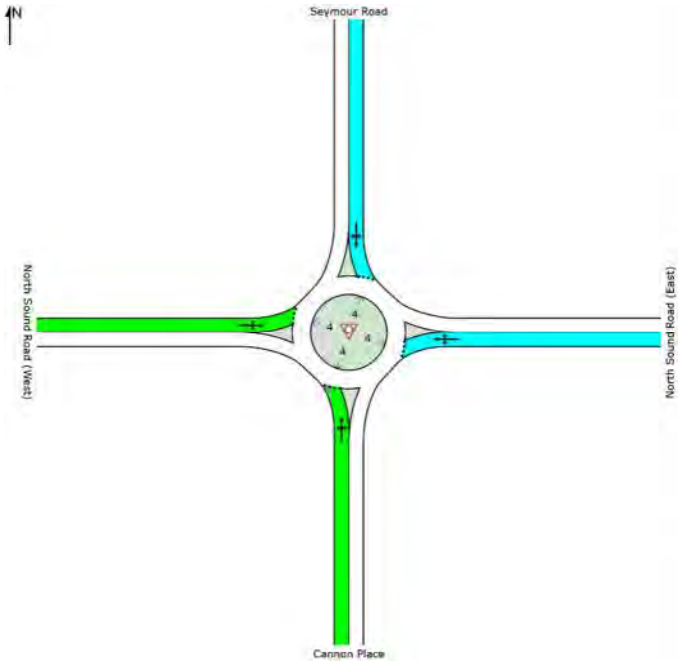

Figure 39 - Sidra Model – Seymour Road roundabout - 2026 - PM Peak - Lane LOS

The approach / lane LOS for the North Sound Road / Dorcy Drive mini-roundabout during the AM and PM peaks are shown in **Figure 40** and **Figure 41.** The results show that all approaches are predicted to continue to operate at LOS A during the peak periods.

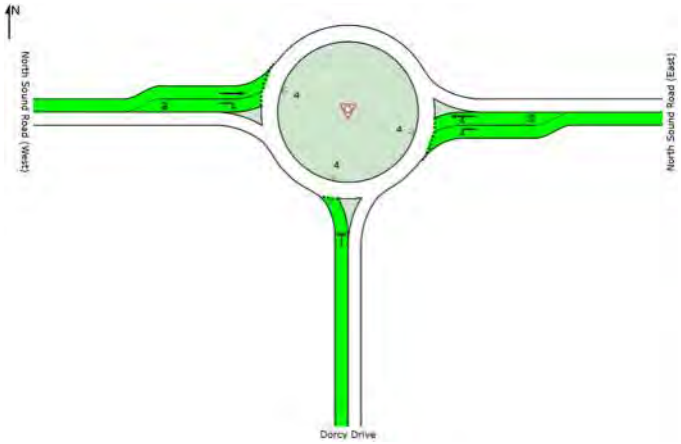

Figure 40 - Sidra Model – Dorcy Drive roundabout - 2026 - AM Peak - Lane LOS

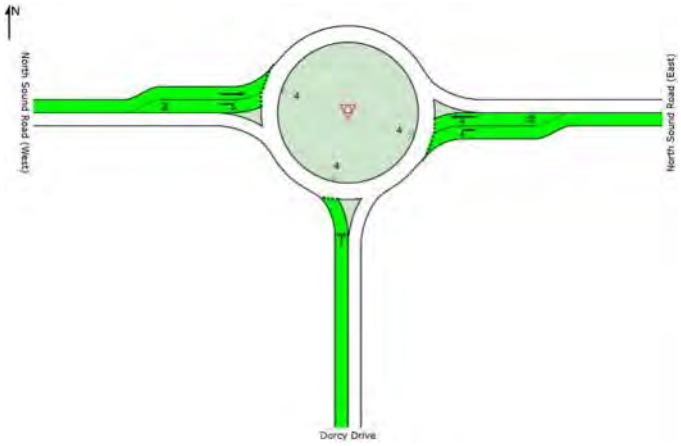

Figure 41 - Sidra Model – Dorcy Drive roundabout - 2026 - PM Peak - Lane LOS

The analysis of the North Sound Road network as a whole, which includes the three intersections, shows that the network will continue to be affected by the capacity issues at BOB roundabout. Refer to **Figure 42** for the AM peak hour analysis results and **Figure 43** for the PM peak hour results. Interrogation of the analysis results shows that the 95% percentile queue length on the North Sound Road (East) approach is predicted to increase to 220 vehicles during the AM peak hour, equating to an estimated distance of over 1.0 mile and 441 vehicles during the AM peak hour, equating to an estimated distance of nearly 2.0 miles. This will significantly impact the operation of North Sound Road through the study area.

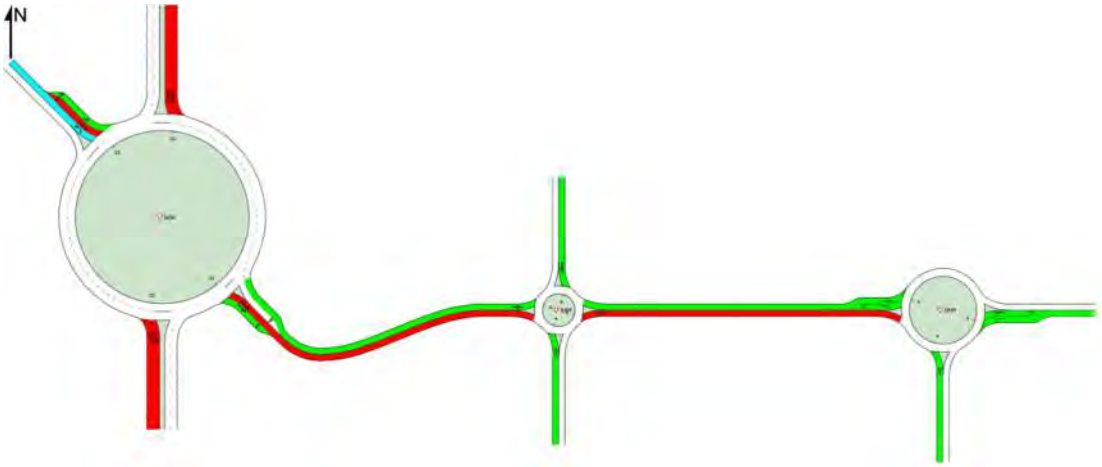

Figure 42 – Sidra Model - North Sound Road Network - 2026 - AM Peak - Lane LOS

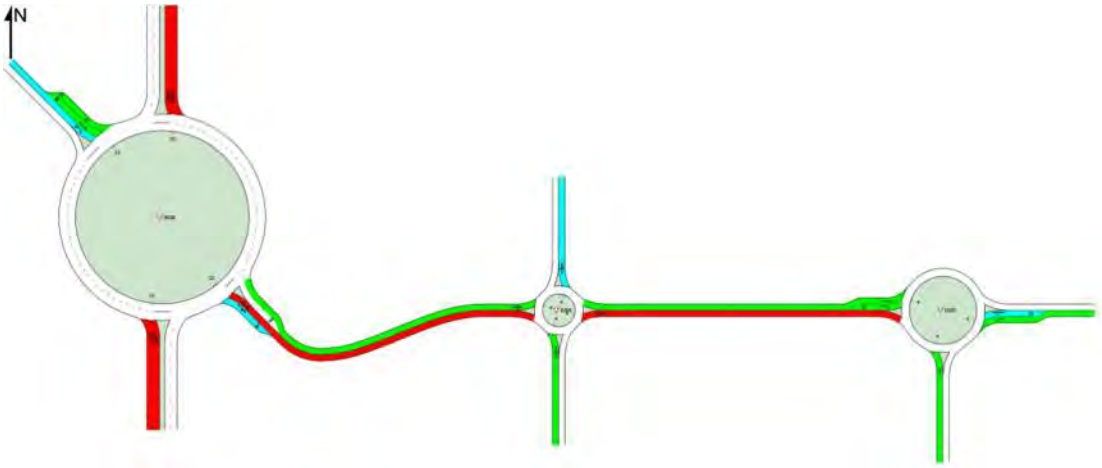

Figure 43 – Sidra Model - North Sound Road Network – 2026 - PM Peak - Lane LOS

4.6.2 NEAR-TERM ASSESSMENT HORIZON - 2031

The three main intersections on the surrounding road network were analysed individually and as well as part of the overall North Sound Road network. Refer to **Figure 44** through **Figure 51** showing the predicted Level of Service for each approach / lane to each intersection for the 2031 Near-Term assessment horizon.

The approach / lane LOS for BOB roundabout during the AM and PM peaks are shown in **Figure 44** and **Figure 45**, respectively. The results show that the North Sound Road (East) approach, as well as other approaches, will continue to experience significant capacity issues due to background traffic growth.

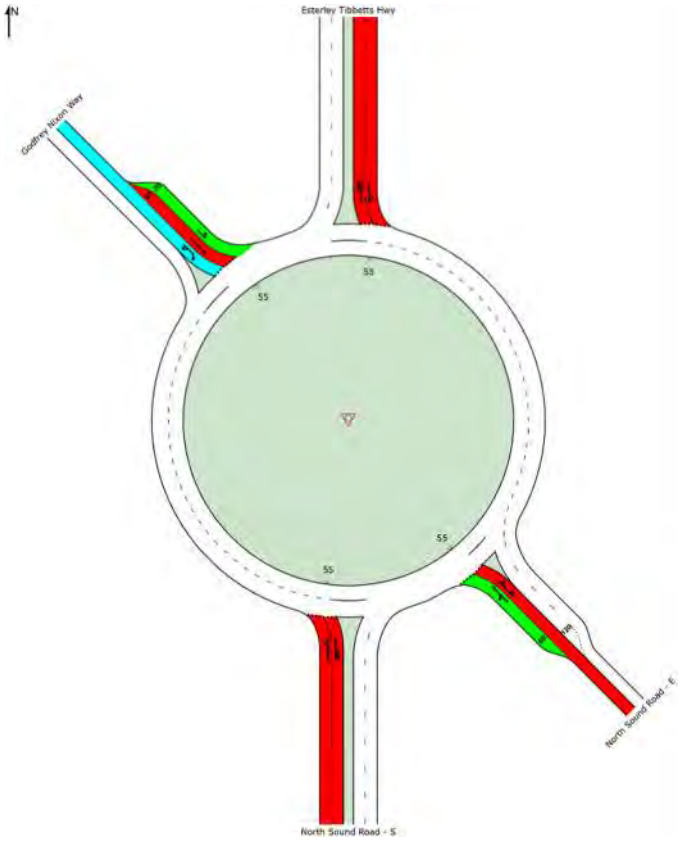

Figure 44 - Sidra Model – Bank of Butterfield roundabout - 2031 - AM Peak - Lane LOS

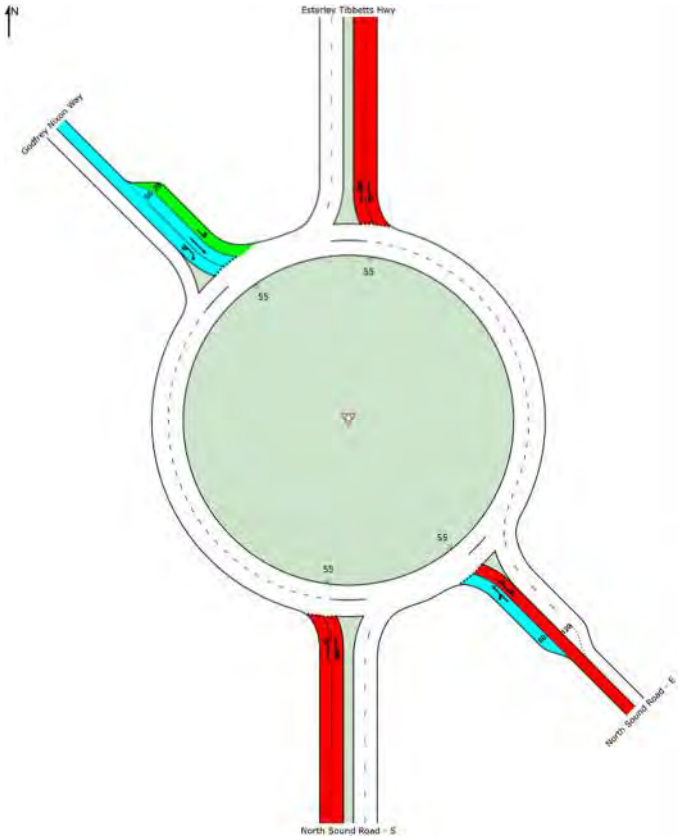

Figure 45 - Sidra Model – Bank of Butterfield roundabout - 2031 - PM Peak - Lane LOS

The approach / lane LOS for the North Sound Road / Seymour Road mini-roundabout during the AM and PM peaks are shown in **Figure 46** and **Figure 47**. The results show that the Seymour Road and North Sound Road (East) approaches are predicted to experience LOS B with other approaches operating at LOS A.

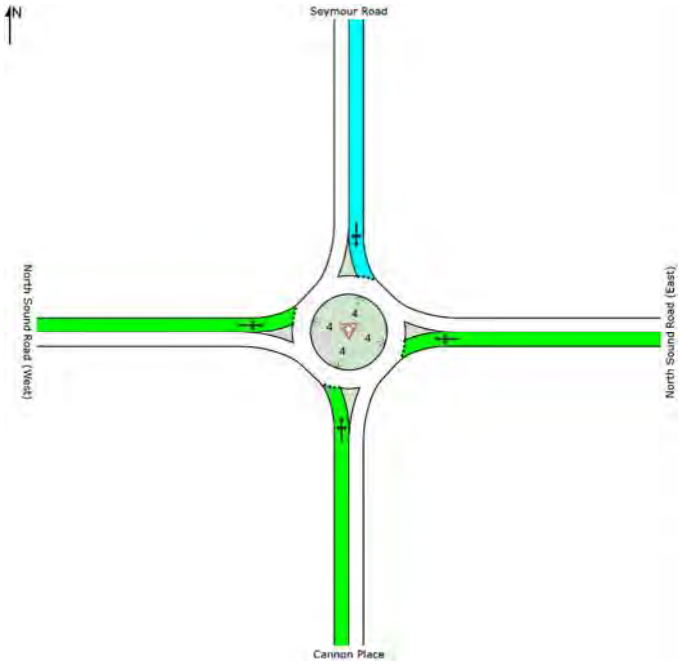

Figure 46 - Sidra Model – Seymour Road roundabout - 2031 - AM Peak - Lane LOS

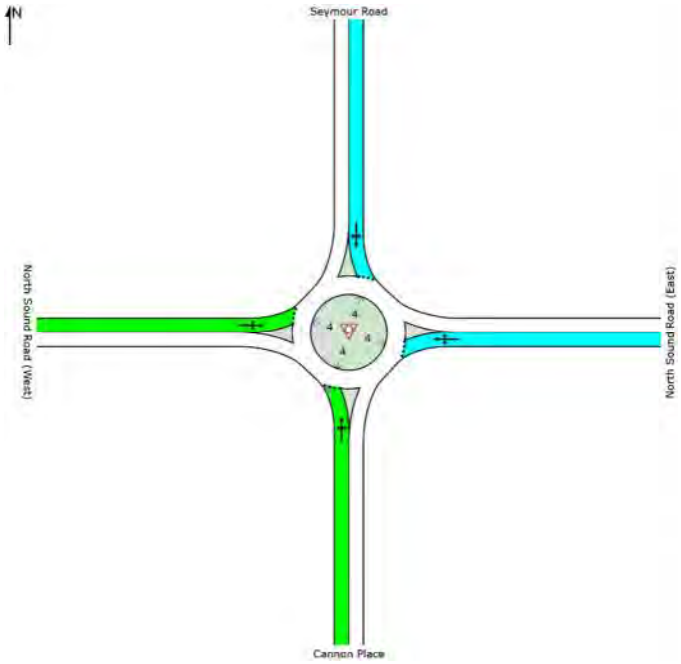

Figure 47 - Sidra Model – Seymour Road roundabout - 2031 - PM Peak - Lane LOS

The approach / lane LOS for the North Sound Road / Dorcy Drive mini-roundabout during the AM and PM peaks are shown in **Figure 48** and **Figure 49**. The results show all approaches will continue to operate at LOS A during the peak periods.

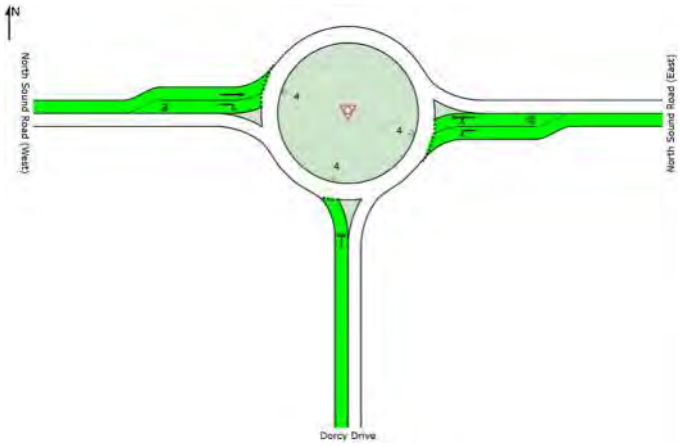

Figure 48 - Sidra Model – Dorcy Drive roundabout - 2031 - AM Peak - Lane LOS

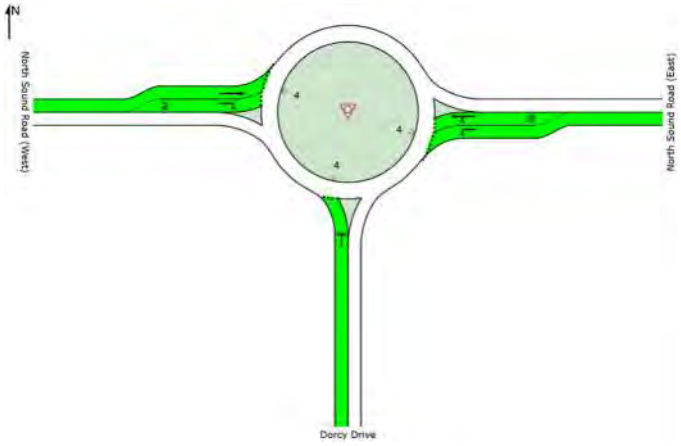

Figure 49 - Sidra Model – Dorcy Drive roundabout - 2031 - PM Peak - Lane LOS

The analysis of the North Sound Road network as a whole shows that the network will continue to be affected by the capacity issues at BOB roundabout. Refer to **Figure 50** for the AM peak hour analysis results and **Figure 51** for the PM peak hour results.

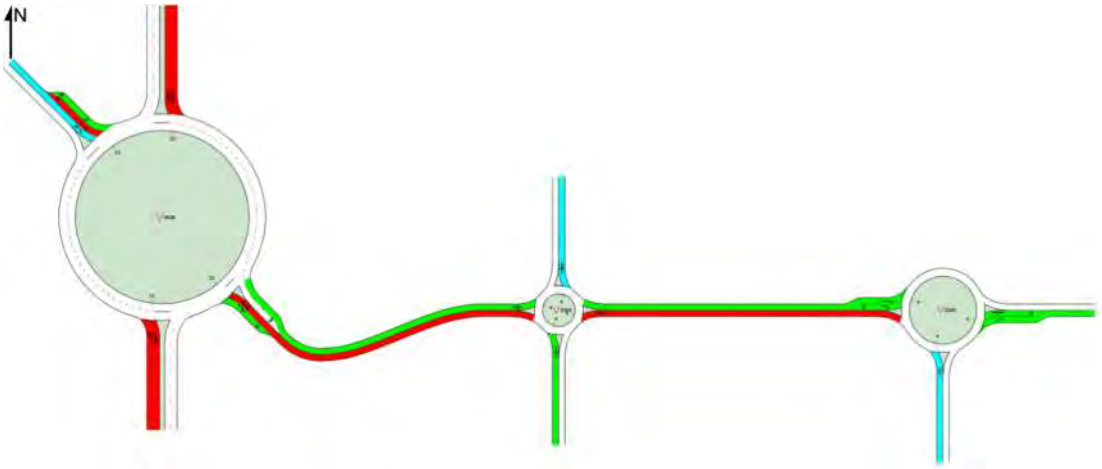

Figure 50 – Sidra Model - North Sound Road Network - 2031 - AM Peak - Lane LOS

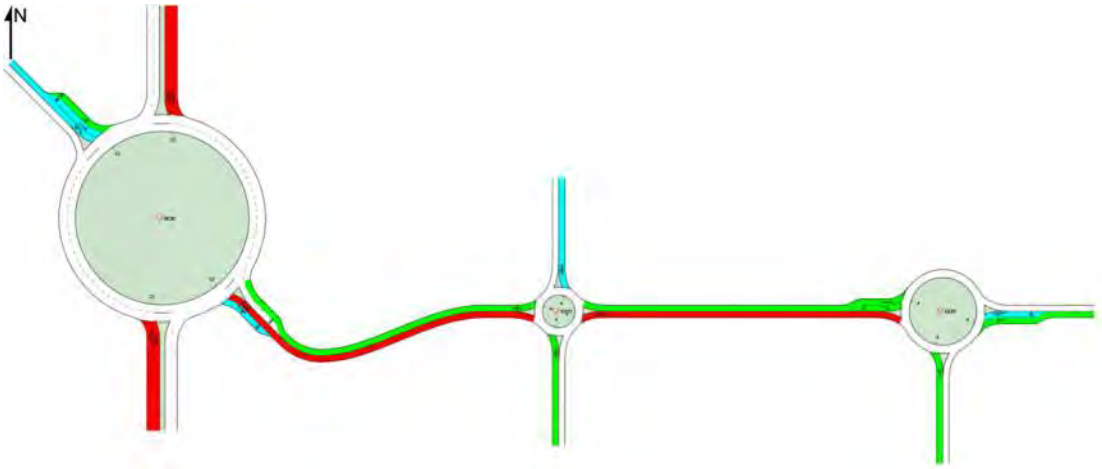

Figure 51 – Sidra Model - North Sound Road Network – 2031 - PM Peak - Lane LOS

4.6.3 MEDIUM-TERM YEAR ASSESSMENT HORIZON- 2036

The three main intersections on the surrounding road network were analysed individually and as well as part of the overall North Sound Road network. Refer to **Figure 52** through **Figure 59** showing the predicted Level of Service for each approach / lane to each intersection for the 2036 Near-Term assessment horizon.

The approach / lane LOS for BOB roundabout during the AM and PM peaks are shown in **Figure 52** and **Figure 53**, respectively. The results show that the North Sound Road (East) approach, as well as other approaches, will continue to experience significant capacity issues due to background traffic growth.

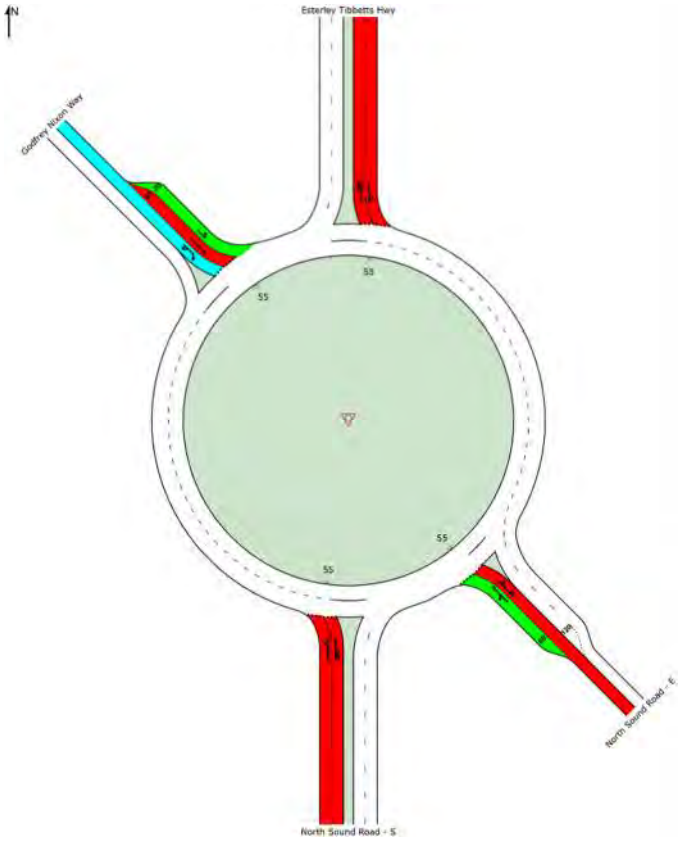

Figure 52 - Sidra Model – Bank of Butterfield roundabout - 2036 - AM Peak - Lane LOS

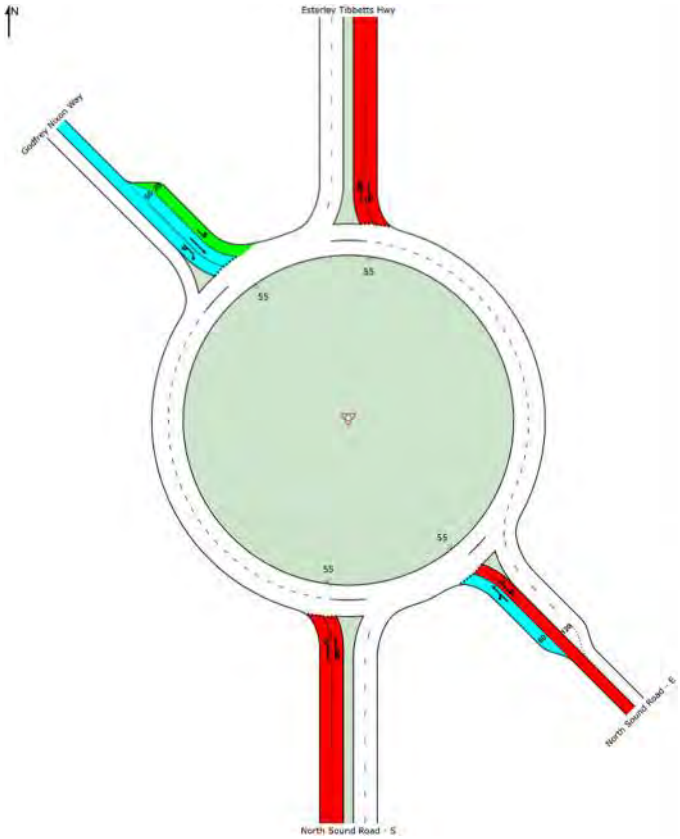

Figure 53 - Sidra Model – Bank of Butterfield roundabout - 2036 - PM Peak - Lane LOS

The approach / lane LOS for the North Sound Road / Seymour Road mini-roundabout during the AM and PM peaks are shown in **Figure** 54 and **Figure 55**. The results show that most approaches will reduce to LOS B during the peak periods, with the North Sound Road (East) approach degrading to LOS E during the PM peak.

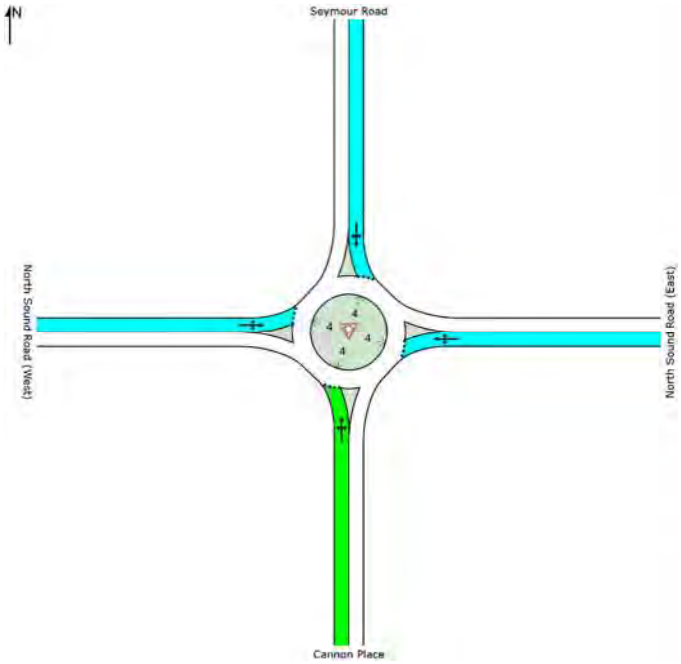

Figure 54 - Sidra Model – Seymour Road roundabout - 2036 - AM Peak - Lane LOS

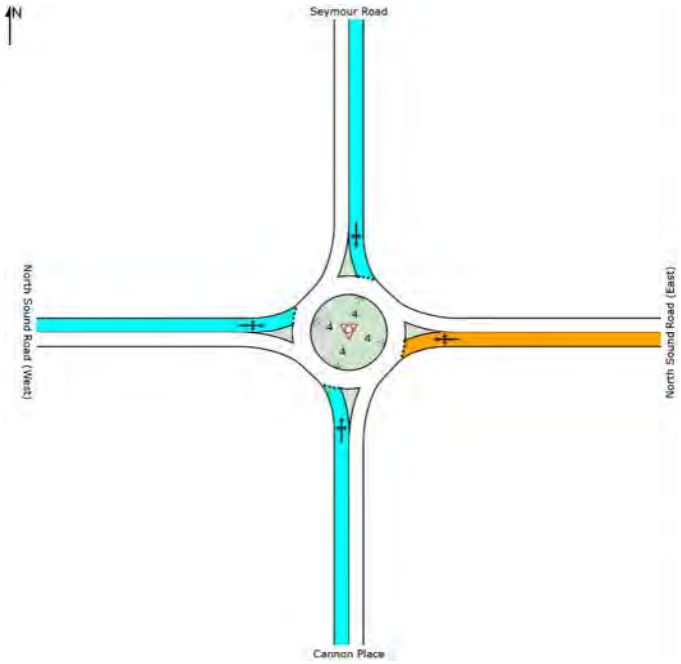

Figure 55 - Sidra Model – Seymour Road roundabout - 2036 - PM Peak - Lane LOS

The approach / lane LOS for the North Sound Road / Dorcy Drive mini-roundabout during the AM and PM peaks are shown in **Figure 56** and **Figure 57**. The results show that some approaches are predicted to degrade to LOS B during the AM and PM peak periods.

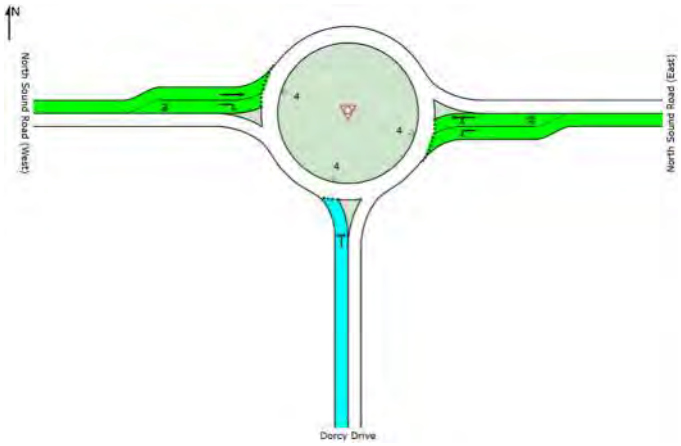

Figure 56 - Sidra Model – Dorcy Drive roundabout - 2036 - AM Peak - Lane LOS

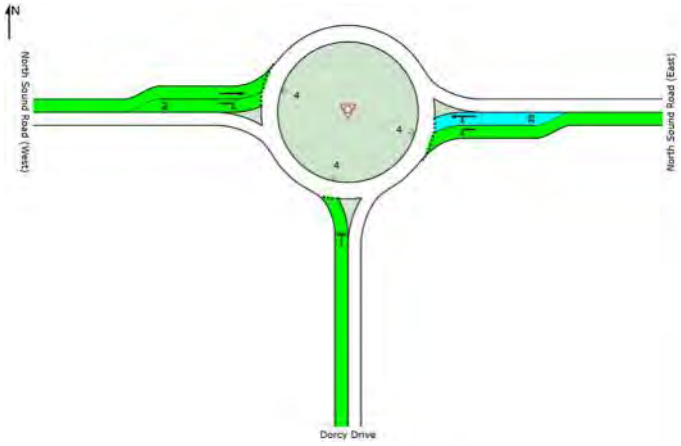

Figure 57 - Sidra Model – Dorcy Drive roundabout - 2036 - PM Peak - Lane LOS

The analysis of the North Sound Road network as a whole, which includes the three intersections, shows that the network will continue to be affected by the capacity issues at BOB roundabout. Refer to **Figure 58** for the AM peak hour analysis results and **Figure 59** for the PM peak hour results. Interrogation of the analysis results shows that the 95% percentile queue length on the North Sound Road (East) approach is predicted to increase to 416 vehicles during the AM peak hour, equating to an estimated distance of over 1.9 miles and 639 vehicles during the AM peak hour, equating to an estimated distance of nearly 2.9 miles. This will significantly impact the operation of North Sound Road through the study area.

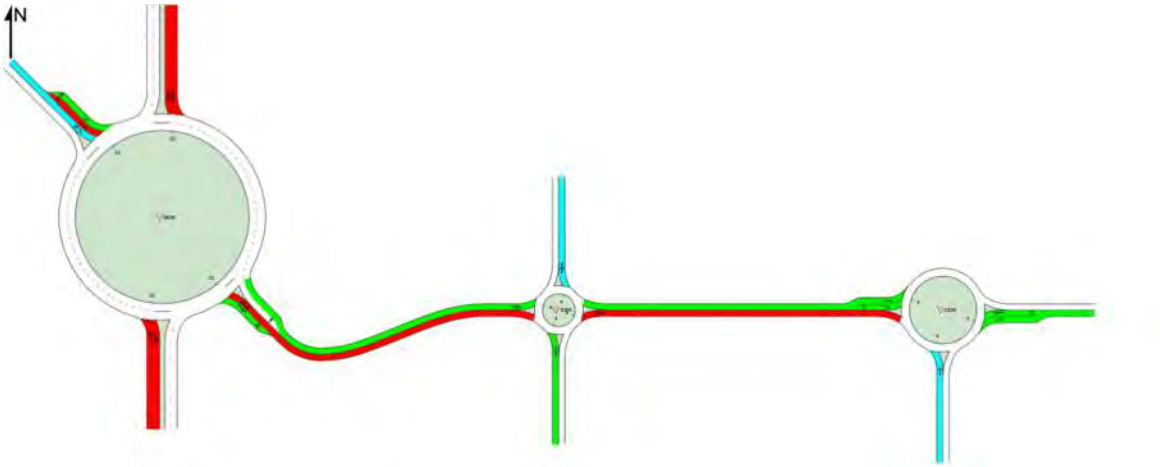

Figure 58 – Sidra Model - North Sound Road Network - 2036 - AM Peak - Lane LOS

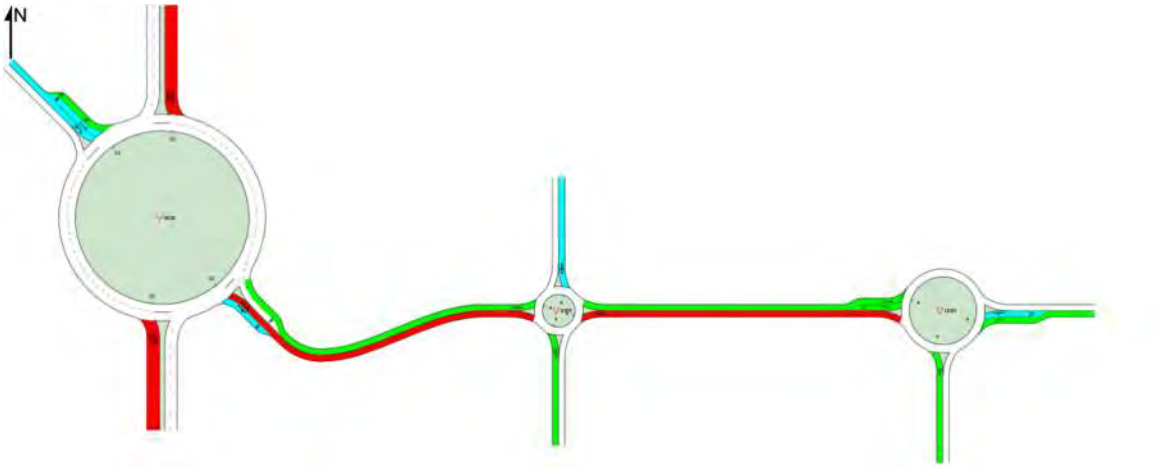

Figure 59 – Sidra Model - North Sound Road Network – 2036 - PM Peak - Lane LOS

4.7 Impact Analysis

The analysis sections above show that the existing road network will continue to experience significant degradation in future years with future predicted traffic growth due to population increase and growing car ownership. The ReGen facilities are not expected to have a direct impact on surrounding road network.

The opening of the Airport Connector Road is likely to reduce traffic flow on the North Sound Road, however an assessment of that impact is outside the scope of this report.

4.8 Mitigation

There are limited strategies available to improve traffic flow through the study area. As has been shown, the capacity issues on the surrounding road network are not as a result of the ReGen facilities and will progressively degrade over the coming years. One method of mitigating the impact of the ReGen facilities on the surrounding road network would be to encourage staff and other landfill associated traffic to access the site outside the peak periods of the network. We have determined from the traffic data available that this already occurs. The peak traffic flows associated with the GTLF occur mostly outside the peak traffic periods of the surrounding intersections / roads – any temporary fluctuations in traffic flow at the GTLF entrance will not impact peak hour operation of the rest of the road network within the study area.

4.9 Environmental Impact

Any possible environmental impacts associated with transportation will be addressed in the relevant section of the EIA.

4.10 Construction Impacts

Based on discussions with the design team, it is understood that the intention is that all ReGen facilities will come online at approximately the same time. It is anticipated that design, engineering, procurement, and construction – including site preparation and auxiliary works for the ERF will take approximately two and a half years. It is anticipated that design, engineering, procurement, and construction for the non-ERF facilities will take approximately one and a half years.

The construction works are likely to include:

- Site preparation, incorporating clearance works, site levelling, demolition, and earthworks
- Piling and foundation works
- Erection of buildings
- Internal road construction
- Underground and overhead utility works

It is expected that at its peak activity period approximately 300 construction staff would be required to construct the ReGen facilities including the associated buildings. The construction phase is a temporary condition, and the 300 personnel will only be on site during the peak construction stage. Typical construction working hours in the Cayman Islands are from 07:00 - 16:00. Based on this, the majority of the construction personnel will be travelling during the morning (AM) peak period and will partially straddle the evening (PM) peak period.

It can be expected that construction personnel will travel to site using multiple models of transport - private vehicle, shared trips (multi-occupancy vehicles), bicycle and some public transport and on foot. For the purposes of analysis, we have assumed that of the 300 staff, 150 additional vehicles would be added to the traffic along North Sound Road & Seymour Road during the peak periods. This is consistent with transportation patterns on construction sites on Grand Cayman. DECCO provided the following feedback:

"I have spoken to two of the DECCO senior project managers who are looking after two of our current construction projects (Indigo and Hospital). Both believe that 50%-60% of construction staff drive to work with the remaining majority car sharing and a smaller proportion utilizing public bus. Some existing sub-contractors do also have a company specific bus service for their staff"

It can be anticipated that the construction personnel will travel to the site in distribution similar to those already travelling on North Sound Road.

Figure 60 and **Figure 61** show the resulting LOS for Seymour Road roundabout for the base year (2022) with construction traffic during the AM & PM peak periods, respectively. In order to undertake a robust analysis of the construction impacts, all construction traffic is modelled to utilise the network during the peak periods. The addition of the construction traffic reduces the LOS on the North Sound Road (East) approach from LOS B to LOS C during the AM peak. During the PM peak, the LOS on Seymour Road is reduced from LOS B to LOS C. It can be seen that the inclusion of additional traffic related to construction of the ReGen facilities has some minor impacts on the surrounding road network.

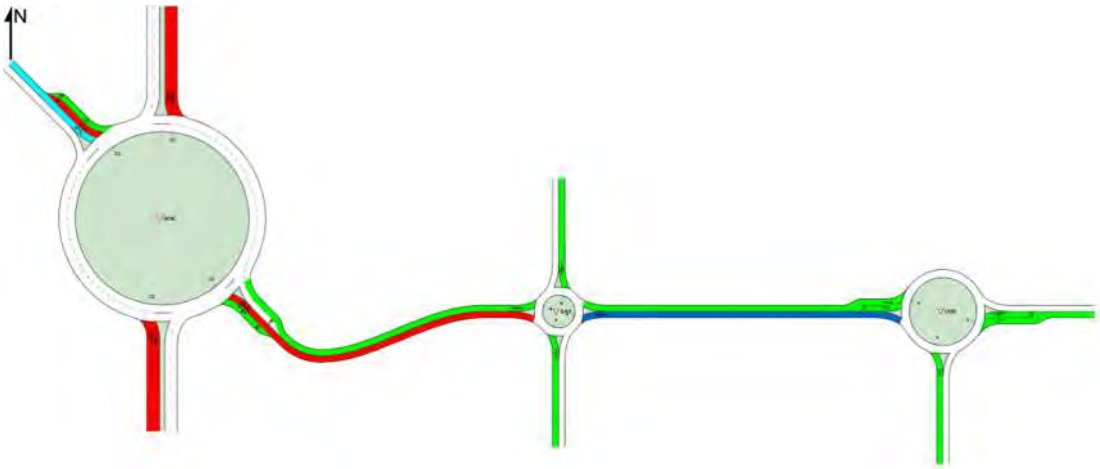

Figure 60 – Sidra Model - North Sound Road Network - Base Year with Construction Traffic AM Peak - Lane LOS

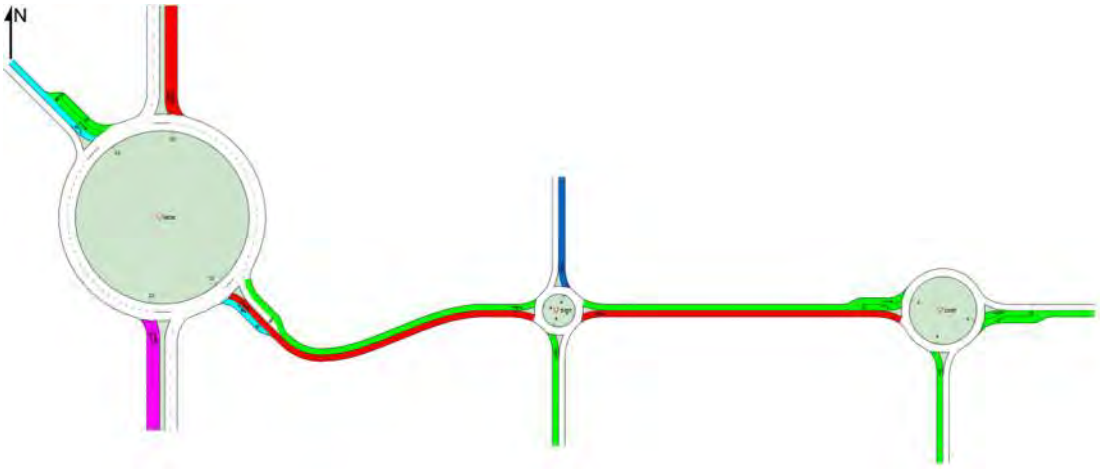

Figure 61 – Sidra Model - North Sound Road Network - Base Year with Construction Traffic PM Peak - Lane LOS

The construction process will require machinery on site as well as vehicle and truck movements on the surrounding road network. Forecasts of the construction traffic prepared by the design team currently expect that approximately 37 HGVs per day will travel to / from the ReGen site during the pile-construction stage of the project. It is expected that most construction delivery movements on the surrounding road network will occur outside the peak traffic flow periods. Based on this and the analysis above, it can be deduced that the construction delivery traffic will cause negligible impact on the surrounding road network. Movement of any large industrial equipment to the site during construction will be managed by specific plans that will consider Health & Safety and protection of any utilities along the path.

5.0 FINDINGS & CONCLUSIONS

The preceding sections provide information on the existing road network surrounding the proposed ReGen facilities and detail the current operation of the GTLF and proposed operation of the ReGen facilities. A detailed assessment of the traffic and road related aspects of the proposed development is undertaken, including a discussion on the expected trip generation of the facility. Finally, a capacity assessment is provided for the three intersections within the study area that could be impacted by the proposed development. Future traffic flows within the study area have been calculated for the Opening Year (2026), Near-Term Year (2031) and the Medium-Term Year (2036).

The following points summarise the major assumptions underpinning this Traffic Impact Assessment:

- The ReGen facilities operations (operating times, waste collection practices, etc.) are expected to be similar to the existing GTLF operations with a marginal increase in staff numbers compared to existing
- Trip generation by the ReGen facilities is expected to be in line with the trips currently generated by the GTLF. There are no plans to modify the waste collection practices
- Trip distribution to and from the ReGen facilities is expected to be similar to existing trip distribution at the GTLF

The following points summarise the major findings and conclusions of this Traffic Statement:

- The peak traffic flows associated with the GTLF occur mostly outside the peak traffic periods of the surrounding intersections / roads – any temporary fluctuations in traffic flow at the GTLF / ReGen entrance will not impact peak hour operation of the rest of the road network within the study area
- The North Sound Road network in the vicinity of the proposed ReGen facilities is currently operating beyond capacity, with much of North Sound Road and approaches to the Bank of Butterfield roundabout experiencing a Level of Service F
- The intersections within the study area will experience a further deterioration in service in the future due to projected traffic growth for Grand Cayman
- The opening of the ReGen facilities is not expected to have a direct impact on the surrounding road network, as traffic associated with the facility will be in line with existing traffic flows associated with the GTLF
- The construction of the ReGen facilities will cause some minor impacts on the surrounding road network during the peak periods

GRAND CAYMAN PROPOSED INTEGRATED SOLID WASTE MANAGEMENT FACILITY PROPOSED TRAFFIC STATEMENT SCOPING REPORT

1.0 INTRODUCTION

This Scoping Report presents the proposed methodology that will be employed during the preparation of the Traffic Statement for the Grand Cayman proposed Integrated Solid Waste Management Facility (ISWMS), commonly referred to as the ReGen facility. APEC Consulting Engineers Ltd (APEC) will be undertaking a traffic study, analysis of existing and future traffic and an assessment o the potential impacts of the ReGen facility.

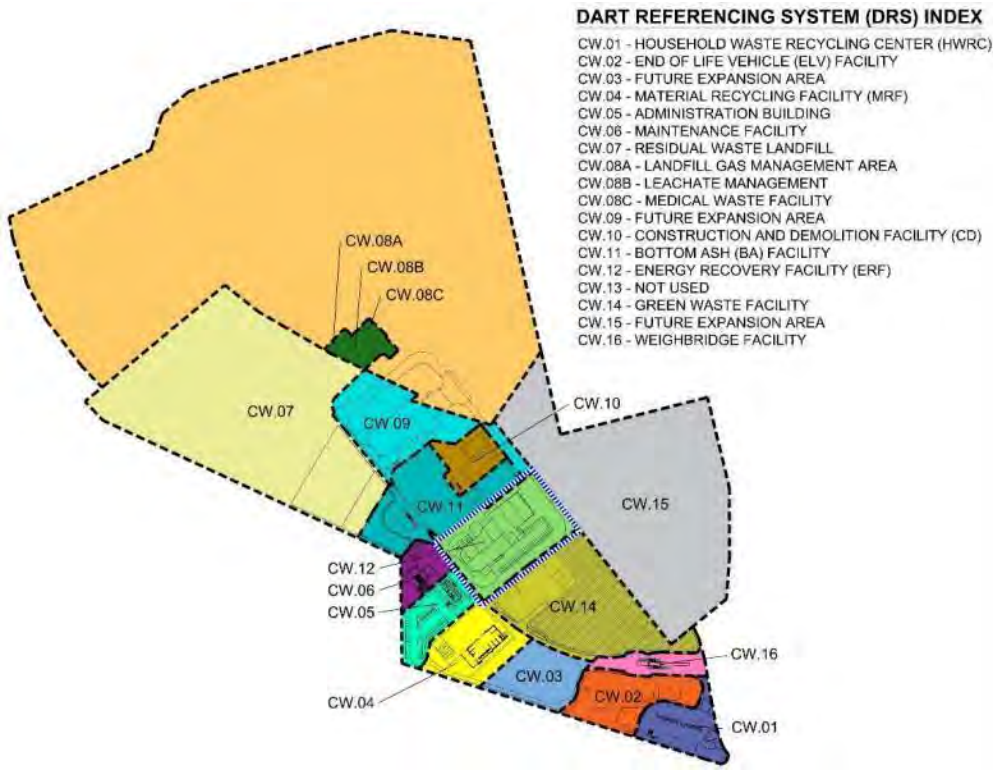

Figure 1 - Proposed Integrated Solid Waste Management Facility Layout

1.1 PROPOSED SCOPE OF ASSESSMENT

As part of the Environmental Impact Assessment (EIA) process, chapter 5.8 of the Terms of Reference (ToR) document outlined the expected procedures for the Traffic Statement. This Scoping Report forms as a development of chapter 5.8 – 'Traffic' of the ToR. The Traffic Statement will follow the National Roads Authority (NRA) requirements 'Terms of Reference and Guidelines for Conduct of Traffic Impact Study in the Cayman Islands, March 2013'.

The EIA shall assess the traffic impacts associated with the ReGen facility on the surrounding road network and assess all possible mitigation measures. This assessment will be presented through a Traffic Statement

(TS). The TS will be organized in such a way as to set out the existing situation, present the proposed development and determine what impact, if any, the site-generated traffic will have on the surrounding road network.

2.0 PROPOSED METHODOLOGY

2.1 Background and Existing Conditions

The TS will provide background information on the proposed project including its location and proponent. The existing road network surrounding the proposed site will be described by way of site plan / map. This will include descriptions of traffic controls of nearby intersections. Details of existing pedestrian, cycle and public transport facilities will also be provided.

2.2 Proposed Development

A summary will be provided of the site development, including proposed energy recovery facility, material recycling & green waste / composting facilities, ancillary buildings, internal access roads, administration building, civil amenity drop-off area, etc. A detailed description of any project construction phasing will be provided.

Other information included as part of this assessment will include:

- Information on likely hours of operation of ReGen facility, number of employees, classification of vehicles on site and estimation of number of vehicles remaining on site and number of vehicles using surrounding road network
- Internal Layout (Traffic circulation, pedestrian routes, visibility and road width, speed control measures)
- Parking (Provision, disabled percentage, layout)
- Public Transport (provision, access from site)

2.3 Study Area

The study area for the TS will consist of an area stretching from the north end of Seymour Road at the entrance to the site, south along Seymour Road and encompass the intersection of Seymour Road with North Sound Road. This encompasses the only available access to the site. The study area referenced in the ToR also included the 'Bank of Butterfield' roundabout intersection at the western end of North Sound Road. As traffic associated with the proposed facility is very likely to be consistent with existing traffic to / from the George Town Landfill, it is not envisaged that the proposed ReGen facility will have an measurable impact on the operation of that intersection and therefore it will not be included in the proposed study area for this TS.

2.3.1 Traffic Data

Data of the traffic flows on the existing road network within the study area will be gathered by way of a combination of automatic traffic counters1 and including turning movement counts undertaken by APEC staff

[1] PicoCount 2500 counter with pneumatic road tubes

and / or associates. It is proposed that traffic data from automatic traffic counters will be collected for a period of at least 7 days at each count site. This traffic data will be analyzed to assess current traffic flow (annual average daily traffic and peak hourly flows), speed and classification through the study area and along Seymour Road.

We will request traffic count data from the 2016 / 2017 NRA island-wide traffic count project. Initial review of the traffic count shows that data should be available for Seymour Road and for the intersection of North Sound Road & Seymour Road. Traffic data is also available from 2012 for Seymour Road at the entrance to the existing George Town Landfill which may be of use in comparison with the more recent data.

Data on the current operation of the existing GTLF will be reviewed, including data from the Department of Environmental Health (DEH), traffic volumes and civic amenity drop-off (including origin information).

A summary will be presented of any committed / proposed road developments in the study area that will be undertaken in the future. In addition, any proposed significant developments that may impact the traffic flows in the study area will be assessed.

2.4 Traffic Analysis

The traffic data from 2016 / 2017 (if available), the data from 2012 along with updated data gathered as part of this study will be analyzed in order to estimate the likely traffic flows associated with the ReGen facility.

An assessment will be undertaken of the existing road capacity based on existing traffic volumes. This assessment will be presented in table format showing the existing capacities on the road network within the study area.

The Traffic Statement will undertake traffic analysis based on the following approach:

- Existing and projected traffic volumes (including turning movements),
- Description of existing road network within study area and any proposed road(s) / accesses
- Traffic controls (where applicable)
- Project trip generation
- Project generated trip distribution and assignment
- Level of service of the existing and of the future / horizon conditions, both with and without the project
- References to other traffic impact studies (as may be necessary)

2.4.1 Trip Generation / Attraction

An estimate will be made of the likely trips generated by the ReGen facility. Peak times of operation will be identified during the day and during the week.

2.4.2 Trip Distribution & Assignment

The directional split of future traffic flows along North Sound Road and Seymour Road will be estimated, based on future trip generation and existing flow distribution.

2.4.3 Assessment Year / Design Year Horizon

The assessment / design year(s) will be selected in order to undertake the traffic impact analysis. We propose to assess the impacts at 5 and 10 years following opening of the facility. Future traffic flows will be calculated based on NRA forecasts for traffic growth. It is proposed that a 3% growth rate be used, however we will review this in line with expected growth rates for waste generation that have been assumed elsewhere in the EIA.

2.5 Impact Analysis

Intersection capacity analysis will be undertaken based on traffic associated with the ReGen facility. Impacts, if any, on the current levels of service will be calculated. The impact on transportation route(s) to and from the new facility will be assessed. Roads (existing and any proposed) that may be affected by ReGen related traffic will be highlighted. If the impact of the ReGen traffic on the surrounding roads (both existing and proposed roads) is greater than a 10% increase then detailed capacity analysis may be required. The scope of this assessment will include both the near-term (Year 5) and overall long-term (Year 10) in order to determine the resulting transportation impacts of the traffic operations on the surrounding road network, particularly during the morning and evening peak hour conditions.

2.6 Mitigation

Roadway improvements or traffic management strategies will be recommended, if required, to mitigate unsafe conditions or increased traffic congestion along transportation routes. Other strategies that may be required could include requiring truck movements to be undertaken during off-peak periods.

2.7 Environmental Impact

Any possible environmental impacts associated with transportation relating to the construction and operation of the ReGen facility will be assessed and mitigations presented.

2.8 Construction Impacts

Likely truck movements required to remove construction & demolition waste from the site and to deliver fill and materials to site during construction will be calculated and presented. An assessment will be undertaken of any abnormal truck loads that may be required as part of the construction works.

APPENDIX B

Section 5.8 of the Terms of Reference of the Environmental Impact Assessment

5.8 Traffic and transport

Introduction

5.8.1 It has been previously established that The Cayman Islands National Road Authority (NRA) consider that the activity is likely to be a low traffic generator and as such a Traffic Impact Assessment will not be required. However, some elements of the transport assessment approach will be needed to inform the operational assessments of the EIA (especially noise and air quality) and this may be contained within a Transport Statement.

Applicable standards and technical guidance

5.8.2 For the traffic and transport statement the following guidance will be used:

- Cayman Island EIA Regulations: National Conservation Council Directive for Environmental Impact Assessments Section 43, National Conservation Law, Extraordinary No.50/2016, June 2016; and
- Terms of Reference and Guidelines for Conduct of TIS in Cayman Islands, Transportation & Planning Unit, National Roads Authority (March 2013).

5.8.3 In addition, it is recommended that the UK Guidance: 1993 Institute of Environmental Assessments (IEA) publication 'Guidance Notes No. 1: Guidelines for the Environmental Assessment of Road Traffic' (the IEMA guidelines) or methodology's similar to these that are based on the assessment of the environmental effects of traffic and transport. IEMA are currently in the process of looking at how this advice can be updated, and it may be supplemented with advice notes that would need to be referred to if issued before the assessment is undertaken.

Baseline conditions

5.8.4 The site is located on the north side of the George Town area of the island with access to the site from the south. The access routes to the site will define the proposed study area.

5.8.5 The study area is defined as the route between the site and Esterly Tibbetts Highway, which has been identified as a strategic route for the Island. It is assumed that traffic to and from the site would arrive at Butterfield Roundabout from the north, west and south of the island and route to the site along North Sound Road and Seymour Road.

5.8.6 The study area incorporates a series of two-lane single carriageway roads and priority junctions/roundabouts, leading to an access into the site which currently terminates with no existing gatehouses or turning head.

Data gathering methodology

5.8.7 An extensive baseline data gathering exercise would be preferable to underpin the statement and ideally this data will include the following:

- Typical baseline traffic flows, percentage HGV and traffic speed data on links in the area (existing data or new traffic surveys). At this stage, it is assumed that Automatic Traffic Counts (ATCs) will be needed on the following links:
  - Site Access Road – Seymour Road, leading onto the Dump Road;
  - Seymour Road – Between the junction with North Sound Road and the site access; and
  - North Sound Road – Between the junction with Seymour Road and Esterly Tibbetts Highway.

- Overview of parking, loading and servicing arrangements at the site;
- Local public bus routes, bus stops and service frequencies;
- Proposed site traffic generation, staff vehicles, waste loads (light and heavy vehicles) – split across daily operating schedules;
- Proposed site construction traffic, number of vehicles, routes of vehicles, types of vehicles and construction staff;
- Destination and origins of the trips to and from the site;
- Type and size of HGV operating out of the site;
- A growth rate to be agreed with the NRA;
- Local pedestrian and cycling facilities, including public rights of way (PRoW); and
- Personal injury accident records on the local highways network.

5.8.8 However, in the absence of this data approximations and extrapolation could be used from data gathered:

- During the NRA 2016 Island Wide Traffic Collection Study at:
  - Intersection ID #8 - ETH / North Sound Rd and Godfrey Nixon Way (Butterfield Roundabout);
  - Intersection ID #28 - North Sound Rd and Dorcy Dr/Kentsville Dr;
  - Various ATRs.
- During a site visit such as:
  - Information on local public bus routes, bus stops and service frequencies, pedestrian and cycling facilities, including public rights of way (PRoW);
  - Information on the standard of highways to gauge levels of road safety in lieu of personal injury accident records on the local highways network.
- From the scheme plans, such as:
  - An overview of parking, loading and servicing arrangements at the site;
- From the current waste operator (and the intended operator if different), such as:
  - Proposed site traffic generation, staff vehicles, waste loads (light and heavy vehicles) per day with operating hours;
  - Type and size of HGV operating out of the site.
- From the intended construction contractor, such as the number of construction vehicles, routes, types of vehicles and the number of construction staff; and
- From any other historical counts undertaken in the vicinity of the site, possibly as part of another planning application.

5.8.9 As a minimum, the following information will be needed:

- Tonnages of waste to be processed and the site operating hours;
- A site visit; and

- Scheme plans.

Current baseline

Local Highways Network

The Dump Road

5.8.10 The Dump Road is a small, single carriageway unmade / informal road, running in a north-westerly direction off Seymour Road. This will be the point at which access is gained to the proposed ISWMS site.

Seymour Road

5.8.11 Seymour Road is a single carriageway road without road markings which links the North Sound Road with the informal Dump Road (and beyond that, the Cayman waste water treatment works). The road runs through a predominantly commercial/industrial area.

North Sound Road

5.8.12 North Sound Road is a two-lane single carriageway road with central white lines which runs between a roundabout with Esterly Tibbetts Highway and the entrance into George Town Yacht Club. The road runs through an area of industrial, commercial and residential land uses and has numerous junctions with minor roads. The road also currently provides access to the airport and numerous other key facilities on the coast as well as access into the commercial/industrial area where the proposed development is located.

Pedestrian and cycle facilities

5.8.13 There are 108 official PRoW on Grand Cayman most of which are relate to beach access. Details of these PRoW will be needed as part of the baseline data collection.

5.8.14 The local roads in the industrial estate do not have paved footways on the side of the carriageway but online photograph would indicate that users do walk in the carriageway on the Island. There are more formal footways provided on both sides of North Sound Road.

5.8.15 There are no designated cycle routes on the Island of Grand Cayman. There are some tourist routes which are advertised such as the Western Loop but none of these overlap the study area.

Bus, rail and air

5.8.16 A public mini-bus transport system connects all districts of Grand Cayman. The buses can be identified by numbers in a coloured circle and the nearest route to the proposed site is the Fuchsia Route (5A and 5B) which provides a loop that includes the Farmers Market, the International Airport and the Cayman Water Authority. These services run every 30 minutes.

5.8.17 The purple route (WB3) runs north south along North Shore Way and Easterly Tibbetts Highway and runs every 15 minutes.

5.8.18 In general bus services runs Monday to Thursday 06:00 to 23:00 and Friday and Saturday between 06:00-01:00. There are some limited services on a Sunday.

5.8.19 There are no railway lines on Grand Cayman, and the International Airport is located approximately 2.5 km as the crow flies south of the proposed development site.

Future baseline

5.8.20 The local road network is being improved and construction is underway to construct the $34 million, two-mile Airport Connector Road. This road is proposed to link the Camana Bay South Roundabout (Esterly Tibbetts Highway) and the Airport via a route passing to the north of the site before heading south to North Sound Road and then on to the Airport. The provision of this road will relieve the Esterly Tibbetts Highway and North Sound Road (west of Butterfield Roundabout) which are key routes proposed to be used by the operational traffic of the proposed development.

5.8.21 It is also noted that there will be a degree of background traffic growth because of population growth and car ownership growth on the Island. The NRA will be contacted to discuss:

- an agreed growth rate for the assessment; and
- details of any significant local developments that need to be considered; and
- any other highway schemes relevant to the study area.

Consultation

5.8.22 A discussion with the Cayman Islands NRA and EAB will be required to discuss a range of issues set out in the baseline and future baseline assessment sections above. One area for clarification will be the inclusion or exclusion of the Planned Development Area for Camana Bay and the proposed Cruise Berthing Facility within the baseline conditions, which at this stage should not be considered in the cumulative impact baseline for assessment.

Scope of the assessment

Potential receptors

5.8.23 As set out within the baseline section above the scope of assessment has been identified as the routes from the strategic Esterly Tibbetts Highway to the site access via local roads which are described within the current baseline section - see **Figure 5.7: Study area for transport assessment.**

5.8.24 The receptors on these roads will be the land uses adjacent to the carriageway and users of the roads.

5.8.25 It should be noted however that during the consultation with the NRA the scope of assessment will be discussed, and it may be widened depending on site specific details that the NRA may set out.

5.8.26 Table 5.41 sets out the initial locations of receptors. Should further receptors be identified their sensitivity to traffic flow will be determined according to the following examples:

- receptors of high sensitivity to traffic flow include schools, accident clusters and roads without footways/sidewalks that are used by pedestrians;
- receptors with medium sensitivity to traffic flow include congested junctions, shopping areas and roads with narrow footways/sidewalks; and
- receptors with low sensitivity include industrial adjacent land uses and places with adequate footway/sidewalk provision.

Table 5.41 Proposed initial receptors and estimated sensitivity

Receptor	Sensitivity	Justification
Seymour Road (from North Sound Road to the Dump Road)	Low	Industrial adjacent land uses
North Sound Road – Between Seymour Road and Esterly Tibbetts Highway	Medium/High	Urban / town centre adjacent land uses

Likely significant effects

5.8.27 The likely significant transport effects that have been taken forward for assessment are summarised in Table 5.42.

Table 5.42 Likely significant transport effects

Activity	Effect	Receptor
Operation and construction traffic increases on local road network	Visual effects	Local road users Adjacent land uses to the carriageway Pedestrian and cyclists
Operation and construction traffic increases on local road network	Driver severance and delay	Other vehicles using the local road network
Operation and construction traffic increases on local road network	Pedestrian severance and delay	Pedestrian using the local roads
Operation and construction traffic increases on local road network	Pedestrian amenity and intimidation	Pedestrian using the local roads
Operation and construction traffic increases on local road network	Accidents and safety	Local road users Adjacent land uses to the carriageway Pedestrian and cyclists
Operation and construction traffic increases on local road network	Hazardous and dangerous loads	Local road users Adjacent land uses to the carriageway Pedestrian and cyclists

5.8.28 The effects scoped out from further assessment are as follows:

- Decommissioning of the facility;
- Capacity of local highways junctions; and
- Ability to convey abnormal loads to site if required.

Assessment methodology

5.8.29 The generic project-wide approach to the assessment methodology is set out in Chapter 4, and specifically in sections 4.2. However, whilst this approach has informed the approach that has been used in this Transport environmental assessment, it is necessary to set out how this methodology has been applied, and adapted as appropriate, to address the specific needs of the Transport assessment.

5.8.30 The traffic and pedestrian inputs (for both the construction and operational phases of the development) used in the EIA will be informed by the baseline data capture exercise and future

traffic flows estimated using a first principals' approach. The magnitude and significance of any environmental traffic and pedestrian effects will be determined and any suitable mitigation identified.

5.8.31 The EIA assessment process will adopt the established methodology as outlined in Guidelines for the Environmental Assessment of Road Traffic (Institute of Environmental Assessment, 1993). The assessment will also be undertaken in consultation with the Proponent and agreement on the following aspects will be sought:

- Identification of sensitive areas / affected parties;
- Forecast traffic levels and characteristics;
- Time(s) suitable for assessment (e.g. AM peak);
- Year of Assessment (year of construction and year of opening); and
- Geographical boundaries of the assessment.

5.8.32 The screening process to define the geographical scope of the EIA study will be based upon the established guidance which recommends that detailed environmental impact studies will only be triggered where road links experience a change in traffic greater than 30% for all vehicles (or HGV) or more than 10% where the links pass sensitive areas. However, as part of this ToR an initial review of the likely receptors to be affected have been made subject to agreement with NRA.

5.8.33 Traffic and pedestrian construction and operational impacts to be assessed will include:

- Driver severance and delay – at junctions or links subject to traffic flow increases which are either approaching capacity, or are over capacity (or delays resulting from traffic diversions);
- Pedestrian severance and delay – at locations where physical obstructions or increases in traffic flows more than 30% are forecast to result in an increase in severance;
- Pedestrian amenity / intimidation – at junctions or links subject to substantial increases in traffic flow in conjunction with any changes in footway widths or crossing facilities. The presence of sensitive user groups will also be considered;
- Accidents and safety – links and junctions (for which data is available) with existing accident rates more than national averages which may be subject to an increase in traffic flows; and
- Hazardous and dangerous loads – consideration of estimated number and composition of loads and assessment of accident risk if considered significant.

5.8.34 The criteria for evaluation will be based on Table 5.41 for the sensitivity of receptors and Table 5.43 for the magnitude of change.

Table 5.43 Guidelines for the Assessment of Impact Magnitude

	Magnitude of Impact			
Magnitude of Change	**Very Low**	**Low Medium**	**Medium**	**High**
Severance	Change in total traffic or HGV flows of less than 30%	Change in the total traffic or HGV flows of 30%-60%	Change in total traffic or HGV flows of 60%-90%	Change in total traffic or HGV flows of over 90%
Pedestrian and Cycle Delay	A professional judgement based on the routes in the context of the individual characteristics			
Pedestrian Amenity	Change in total traffic or HGV flow of <100%	A professional judgement based on the routes with >100% change in context of the individual characteristics		
Cyclist Amenity	Change in total traffic or HGV flow of <100%	A professional judgement based on the routes with >100% change in context of the individual characteristics		
Accidents and Safety	A professional judgement based on the level of baseline collision numbers and severity of collisions as well as the predicted change in collisions.			

5.8.35 Identified adverse effects will be categorised as 'slight', 'moderate' or 'substantial' as appropriate using the matrix presented in Table 5.44; with substantial, moderate/substantial and moderate classed as significant.

Table 5.44 Establishing the Level of Effect

	Sensitivity of receptors		
Magnitude of Change	**High**	**Medium**	**Low**
High	Substantial	Moderate/Substantial	Moderate
Medium	Moderate/Substantial	Moderate	Slight/Moderate
Low Medium	Moderate	Slight/Moderate	Slight
Very Low	Slight	Slight/Negligible	Negligible

5.8.36 Any departures from the guidelines will be agreed with the Proponent and will be clearly stated within the Environmental Statement. Mitigation will also be developed in consultation with the Proponent and will adopt the hierarchical principles of prevention, reduction and offsetting if required at all.

Inputs to other EIA Topics

5.8.37 The traffic team will supply existing and forecast data and analysis, relating to peak and average flows, Annual Average Daily Traffic (AADT) flows and traffic speeds, to inform other assessments within the EIA such as noise and air quality as required.

Socio-Economic Impact Assessment

ISWMS for the Cayman Islands

Socio-Economic Impact Assessment

ReGen and Cayman Islands Government

4 August 2023

The Power of Commitment

Contents

1. Introduction **1**
1.1 Purpose of this report 1
1.2 Overview of the proposed development 1
1.2.1 Key features 1
1.2.2 Workforce 2
1.2.3 Timeframes 2
1.3 Structure of report 4
1.4 Scope and limitations 4
1.5 Limitations 4
2. Applicable legislation, policies and guidelines **5**
3. Methodology **7**
3.1 Scoping 7
3.2 Study area 8
3.3 Establishing the socio-economic baseline 8
3.4 Consultation 9
3.4.1 SEIA consultation 9
3.5 Description and assessment of impacts 9
3.5.1 Characterise the socio-economic impact 10
3.5.1.1 Nature 10
3.5.1.2 Temporal extent 10
3.5.1.3 Spatial context 10
3.5.2 Assess the significance 10
3.6 Development of management measures 12
4. Stakeholder consultation **13**
4.1 SEIA consultation 13
5. Baseline conditions **15**
5.1 Project footprint and immediate surrounds 15
5.2 Local and regional study area 16
5.2.1 Overview of the study area 16
5.2.2 Demographic profile 16
5.2.2.1 Population 16

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

1. Introduction

1.1 Purpose of this report

GHD Limited was retained by ReGen and the Cayman Islands Government (CIG) as approved by the Environmental Assessment Board (EAB) to undertake a socio-economic impact assessment (SEIA) as part of the Environmental Impact Assessment (EIA) for the proposed Integrated Solid Waste Management System (ISWMS, Project). The SEIA has been prepared to address the socio-economic requirements of the ISWMS for the Cayman Islands: Environmental Impact Assessment Terms of Reference (ToR) prepared by the proponent.

In line with ToR for project, the objectives for the SEIA are to 'consider the way in which the proposed development will affect people's way of life, their community, economic activity and culture'. Specifically, the SEIA:

– Describes the existing socio-economic conditions of the study area.
– Identifies potential socio-economic benefits and adverse impacts of the development, during construction and operation, and assesses their significance.
– Outlines measures that will be undertaken by the proponent to enhance socio-economic benefits and mitigate and/or manage negative socio-economic impacts of the project.

The SEIA has been informed by the outcomes of stakeholder consultation conducted for the SEIA. It also includes consideration of the results of other technical studies prepared for the EIA, including Landscape and Visual (Chapter 10), Air Quality (Chapter 11), Noise and Vibration (Chapter 12), and Traffic and Transport (Chapter 13).

The SEIA has further been guided by the International Association for Impact Assessment's Guidance for Social Impact Assessment (Vanclay et al., 2015).

1.2 Overview of the proposed development

Each year, approximately 115,000 tons of solid waste is produced in the Cayman Islands, with the overwhelming majority of the material presently being managed by the George Town landfill (GTLF). This landfill capacity is, however, finite and in accordance with the provisions of both the National Solid Waste Management Strategy for the Cayman Islands (2016) and the National Planning Framework (draft for public consultation) (2018), the ToR has been prepared in relation to the proposed development of a replacement ISWMS for the Cayman Islands.

The proposed ISWMS site is located to the north of central George Town towards the western coast of Grand Cayman, immediately south-west of the existing GTLF. The proposed ISWMS is a multi-facility development, including an energy recovery facility (ERF) and supporting non-ERF waste processing, treatment, and disposal facilities. Construction and operation of the ISWMS would allow the existing landfills in George Town, Cayman Brac and Little Cayman to be closed and remediated.

1.2.1 Key features

The proposed ISWMS consists of various new waste management facilities, the majority of which are subject to the EIA process. The development also includes some smaller elements that would not on their own attract the need for an EIA but are still considered as part of the overall development in order to assess their 'in combination' effects with the major components of the ISWMS. In this regard, the EIA considers the cumulative effects of all aspects of the ISWMS.

The various components of ISWMS are as follows:

– Energy Recovery Facility (ERF) (subject to EIA)
– Non-Energy Recovery Facilities:
    - Site weighbridges (excluded from the EIA)

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

- Green Waste Processing Facility (subject to EIA)
- Construction and Demolition Waste Processing Facility (subject to EIA)
- Bottom Ash Processing Facility (subject to EIA)
- Abandoned and End of Life / Scrap Metal Processing Facility (subject to EIA)
- Medical Waste Facility (subject to EIA)
- Materials Recycling Facility (excluded from the EIA)
- Household Waste Recycling Centre (excluded from the EIA)
- Landfill Gas Facility (subject to EIA)
- Residual Waste Landfill (RWL) (subject to EIA)

– Ancillary Facilities:
  - Admin Building (excluded from the EIA)
  - Maintenance Building (excluded from the EIA)
  - CUC Substation (excluded from the EIA)

An overview of the location of the ISWMS and its components is shown on Figure 1.1.

A complete description of each of the project elements described above is provided in Chapter 4 (Proposed Project and Overview of Concerns and Constraints) of the EIA.

1.2.2 Workforce

A construction workforce of approximately 300 persons will be required to complete the ISWMS development, over the three-year construction period.

The project is anticipated to result in the creation of approximately 70 full-time positions during operation.

1.2.3 Timeframes

Construction for the proposed ISWMS development would commence in 2024, with completion planned in 2027.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

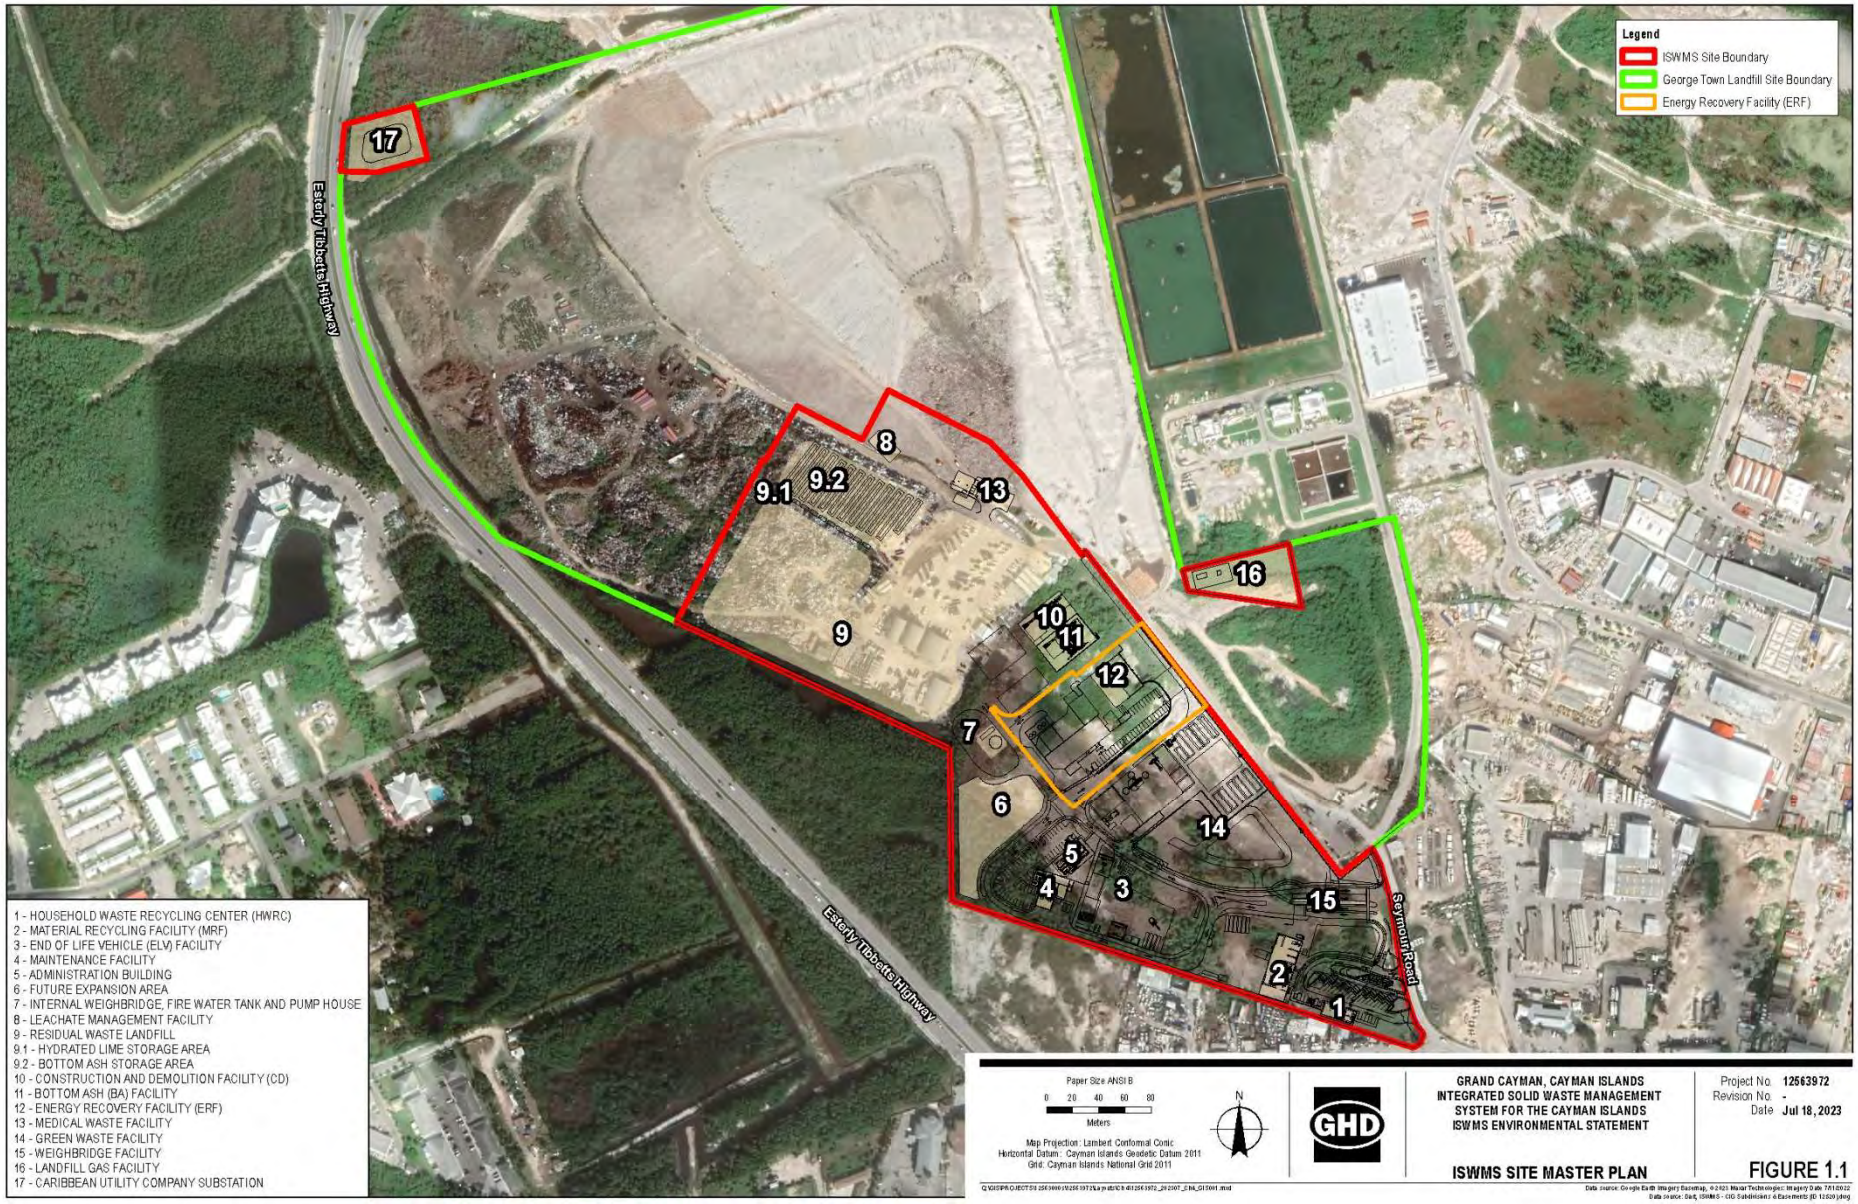

Figure 1.1 ISWMS project site plan

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

1.3 Structure of report

The structure of this SIA is outlined below.

– Section 1 – introduces the report and includes a brief description of the project.
– Section 2 – outlines the relevant legislation and policy applicable to this assessment.
– Section 3 – describes the methodology for the assessment.
– Section 4 – describes the SIA-specific consultation (including outcomes) undertaken for the project.
– Section 5 – describes the existing socio-economic environment for the project.
– Section 6 – identifies the potential social impacts arising from the construction of the project.
– Section 7 – identifies the potential social impacts arising from the operation of the project.
– Section 8 – provides recommended impact management and mitigation measures.
– Section 0 – provides a conclusion for the report.
– Section 10 – provides a list of references used in the report.

1.4 Scope and limitations

This report: has been prepared by GHD for ReGen and Cayman Islands Government and may only be used and relied on by ReGen and Cayman Islands Government for the purpose agreed between GHD and ReGen and Cayman Islands Government as set out in section 1.1 of this report.

GHD otherwise disclaims responsibility to any person other than ReGen and Cayman Islands Government arising in connection with this report. GHD also excludes implied warranties and conditions, to the extent legally permissible.

The services undertaken by GHD in connection with preparing this report were limited to those specifically detailed in the report and are subject to the scope limitations set out in the report.

The opinions, conclusions and any recommendations in this report are based on conditions encountered and information reviewed at the date of preparation of the report. GHD has no responsibility or obligation to update this report to account for events or changes occurring subsequent to the date that the report was prepared.

The opinions, conclusions and any recommendations in this report are based on assumptions made by GHD described in this report (refer section(s) 1.5 of this report). GHD disclaims liability arising from any of the assumptions being incorrect.

1.5 Limitations

The methodology includes the following limitations:

– there is no national guidance on the assessment of socio-economic impacts for the Cayman Islands, however, international best practice guidelines have been adopted as outlined in Section 3.
– the assessment is based on the information provided to GHD at the time of undertaking the SEIA.
– economic data required to undertake the economic impact assessment was not available at the time of preparing this SEIA and therefore, economic impacts have been assessed qualitatively based on desktop information, the project description and through findings from consultation.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

2. Applicable legislation, policies and guidelines

Table 2.1 summarises legislation, policies and guidelines relevant to this assessment.

Table 2.1 Applicable legislation, policies and guidelines

Policy name	Relevance to project
Labour Law (2011 Revision)	The Labour Law (2011 Revision) applies to any employee and/or employer in the Cayman Islands. The Labour Law provides a system of regulations including employment contract, types of leave, minimum wage, severance pay and termination. The project is required to meet the obligations under the Labour Law (2011 Revision), through the employment of the construction and operational workforce.
Workmen's Compensation Law (1996 Revision)	The Workmen's Compensation Law (1996 Revision) provides workers' compensation which is payable to a worker who suffers an injury, disease or death arising from, or during, employment. The project is required to meet the obligations under the Workmen's Compensation Law (1996 Revision), through the employment of the construction and operational workforce.
Tourism Law (1995 Revision)	The Tourism Law (1995 Revision) applies to the Department of Tourism and tourism-related boards and councils, operators licensing and more. This SEIA considers impacts of the project, both beneficial and adverse to the tourism industry of the Cayman Islands.
Cayman Islands Climate Change Policy 2011	The Cayman Islands' Climate Change Policy outlines consensus-based interventions to be implemented. Additionally, the Policy contains measures required to curb greenhouse gas emissions from activities that contribute to the problem of continued climate change. The Policy identifies policy goals and objectives. Under Critical Infrastructure one of the legislative actions to be implemented is to "Climate proof" existing and future waste management sites and designate temporary waste collection sites for storage of hurricane debris/waste. Another key policy goals is to Reduce Greenhouse Gas Emissions, in line with agreed national targets, through promoting energy conservation, reducing energy use and encouraging greater use of renewable energy. This project is proposing to remediate and replace the existing landfill site with an integrated waste management facility as well as provide recycling opportunities for domestic and other waste. This is in line with the aforementioned goals and objectives.
National Tourism Plan 2019-2023	The National Tourism Plan (NTP) provides a road map for enhancing the competitiveness of the Cayman Islands tourism industry and ensuring the sustainability of the islands' cultural and natural assets. The intent of the plan is to maximise and spread the benefits of tourism development throughout the country. The Plan identifies priority issues and challenges to be addressed. Solid Waste Disposal/Recycling was raised as an important and growing issue, revolving around landfills. Several studies have been conducted and alternative approaches proposed, including relocation of the existing landfill on Grand Cayman, development of a waste-to-energy facility, and recycling programmes. There appears to be a strong desire within the industry to improve and increase recycling programmes, but these issues have yet to be resolved. This project is proposing to close the existing landfill in George Town, remediate and replace it with an integrated waste management facility. Therefore, is in line with the aforementioned aspirations.
National Energy Policy 2017-2037	The NEP seeks to establish a framework with which all stakeholders can identify, sets the stage for the achievement of the territory's energy goals and takes into account the imperative to reduce greenhouse gas emissions, thereby lowering the carbon footprint

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Policy name	Relevance to project
	of the Cayman Islands. The Policy focuses on exploiting renewable energy, promotes energy efficiency and conservation measures and supports energy security by reducing the reliance on imported fossil-based fuels. Goal 1 aims to educate people on the impacts of energy demand on the environment. Strategy 3.1.2 - fuel products sector strategy: support jurisdiction-wide and industry developed public education programmes on handling, storage and disposal of waste, aims to support Goal 1. Goal 3 aims to ensure energy security for the Cayman Islands. Under this goal strategy 3.3.11.3 aims to support national waste management policies by facilitating interconnection of waste to energy generation to the grid. The ISWMS facility is proposed to include an ERF which is in line with the aforementioned goals and strategies.

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

3. Methodology

This section presents the methodology adopted for this SEIA. The approach was developed based on the Terms of Reference (Wood, 2021), and best practice methodologies established by relevant standards, polices and guidelines and leading research, including:

– International Principles for Social Impact Assessment 2003 (Vanclay 2003)
– Social Impact Assessment: Guidance for Assessing and Managing the Social Impacts of Projects (Vanclay et al. 2015).

SEIA is broadly defined as the process for 'identifying and managing the socio-economic issues of project development' (Vanclay et al., 2015). The goal of SEIA is ultimately to bring about better project outcomes that benefit both communities and proponent alike, not just the identification or amelioration of negative outcomes (Vanclay, 2003).

In line with this understanding, the assessment process comprised of three phases as shown on Figure 3.1. These steps are explained in further detail below.

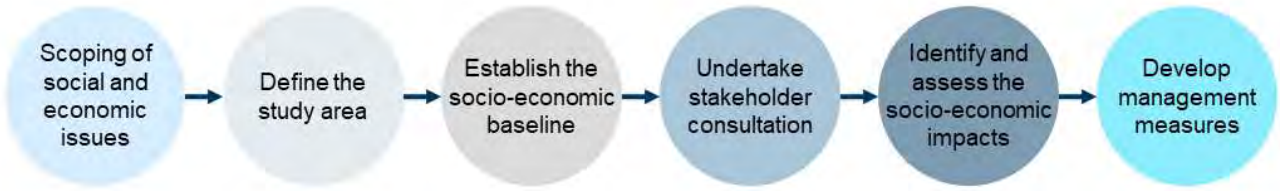

Figure 3.1 Overview of SEIA methodology

3.1 Scoping

The scoping phase involved preliminary planning of the SEIA. This included initial desktop research and consultation with the internal EIA project team to understand the local context, discuss and agree on the SEIA scope, and identify project affected stakeholders.

A key outcome of this phase included agreement on the elements of the socio-economic environment for investigation that may be directly or indirectly changed by the project. These indicators are outlined and defined in Table 3.1 below. These indicators have been adapted from a review of social changes commonly associated with major infrastructure development, in particular waste facilities (Franks, 2012). The structure of the SEIA (i.e., the baseline and impact assessment) reflect these aspects in the sections which follow.

Table 3.1 Elements of SEIA investigation

Element	Definition and scope
Population	The characteristics, mobility and rate of change of populations, including diversity, community composition and rates of influx.
Employment and economy	The availability and accessibility of employment and business development opportunities, and the existence and role of particular industries.
Health and community wellbeing	The ability of people to maintain their health and a lifestyle that is not detrimental to their wellbeing. Also includes the overall wellbeing of a community, including its cohesion and safety, how it functions and people's sense of place.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Element	Definition and scope
Services and infrastructure	The quality, availability and accessibility of social services and infrastructure. This may include (but not limited to) health and emergency services, aged and childcare, utilities, roads network and infrastructure, public transport, housing and accommodation, recreational facilities.
Access and connectivity	The ability of people to maintain access to public spaces or private property and/or their ability to conveniently get from one place to another.

3.2 Study area

The study area is the geographical area of social influence of the project. For the purpose of this study, the study area includes the people and communities who are likely to experience changes to existing socio-economic conditions resulting from the Project.

Table 3.2 presents the study area for the SEIA.

Table 3.2 Description of the study area

Study area	Statistical area	Relevance to Project
Project footprint	N/A	This what is at the site and landholdings in the Project's immediate surroundings.
Local study area	District of George Town	This includes the community of George Town, which is the municipal area containing the Project infrastructure and is likely to be the main source of workers, goods or services for the Project. People in the broader city of George Town are also expected to have a variety of interests and concerns with the Projects.
Regional study area	Cayman Islands	This includes the Cayman Islands as a whole, which is likely to be the focus where economic changes will be most noticeable.

3.3 Establishing the socio-economic baseline

A baseline of the existing social and economic conditions was established for the local study area and regional study area.

This context was used as the basis for considering potential impacts of the project. Existing conditions were determined via a review of:

- Local population census data
- Government planning documents
- International financial institutions' statistics
- Non-governmental organisations (NGOs) and industry reports
- Other assessment reports prepared for projects in proximity to the study area
- GIS mapping
- Information gathered through consultation with stakeholders (Section 4)

All data in Section 5 has been drawn from the Cayman Islands' 2021 Census of Population and Housing Report published in July 2022 and prepared by the Economic and Statistics Office (ESO), unless otherwise stated.

Where required information is not available in the 2021 Census, the baseline assessment has been supplemented by other available reports, including The Cayman Islands' Compendium of Statistics 2020 (ESO, 2021) and The Cayman Islands' Labour Force Survey Report Fall 2022 prepared by the ESO.

The existing conditions describe the social values, economic characteristics and social infrastructure and services that are likely to be affected by the project.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

3.4 Consultation

3.4.1 SEIA consultation

Stakeholder consultation is a critical component of the SEIA process. Internal and external stakeholder consultation was undertaken to inform the SEIA. Prior to consultation being undertaken, a Stakeholder Consultation Plan for approval by ReGen and the Environmental Assessment Board (EAB) was prepared to identify key stakeholders, detail the approach to consultation and identify themes to be discussed during consultation.

SEIA consultation was undertaken between May and June 2023 by the SEIA team via videoconference facilities. Section 4 presents a summary of the consultation activities and outcomes relevant to this assessment.

The overall purpose of the SEIA consultation was to validate and gather additional information to inform the development of the socio-economic baseline, the identification of potential social and economic benefits and impacts, and development of recommended mitigation and management measures. The stakeholders consulted for the SEIA (Table 3.3) were identified because they would have the potential to experience positive or negative social and economic impacts as a result of the project, or because they represent communities and stakeholders who would potentially experience impacts.

Table 3.3 Stakeholders

Stakeholder group	Stakeholders consulted
Government	– Department of Environment (DOE) – Ministry of Sustainability and Climate Resiliency – Ministry of Tourism and Ports – Ministry of health and Wellness
Business / industry organisations	– Cayman Islands Tourism Association (CITA) – Cayman Islands Chamber of Commerce – Island Waste Carriers
Community service providers	– George Town Police Station – Cayman Islands Fire Service
Non-government organisations	– Sustainable Cayman

3.5 Description and assessment of impacts

Following the scoping of socio-economic issues described in Section 3.1, impacts were confirmed using a data triangulation method, whereby multiple sources of information were used to confirm socio-economic impacts. These data sources are summarised below:

– The project description for the EIA to understand the proposed activities that would influence social aspects.
– Baseline conditions against which the social changes/impacts were measured.
– Outcomes of the stakeholder consultation undertaken for the SEIA and the project as a whole to understand the existing environment and stakeholder views on potential social changes brought about by the project.
– Relevant draft and final technical studies prepared for the EIS to gather technically sound evidence to identify and assess the social changes resulting from the project:
    - Air Quality Assessment (Chapter 11)
    - Noise and Vibration Assessment (Chapter 12)
    - The Seascape and Landscape Visual Considerations Report (Chapter 10)
    - Traffic Statement (Chapter 13)

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

The evaluation of the identified social impacts was undertaken using a sensitivity and magnitude significance rating, based on the significance criteria provided in the Terms of Reference and shown in Section 3.5.2.

3.5.1 Characterise the socio-economic impact

In order to place potential socio-economic impacts in context, the nature (beneficial or adverse), the temporal extent (short or long term) and their spatial context (local or national) were considered in accordance with Section 5.9.19 of the Terms of Reference.

The criteria used in considering the nature and type of impact are defined below:

3.5.1.1 Nature

– Beneficial: an impact is considered beneficial if a change represents an improvement from the socio-economic baseline, or if a new and desirable factor is introduced to the socio-economic environment.
– Adverse: an impact is considered adverse if there is a negative change to the socio-economic baseline, or if a new undesirable factor is introduced to the socio-economic environment.

3.5.1.2 Temporal extent

The temporal extent of an impact refers to the time in which the change will take place, and includes:

– Short term: an impact is considered short term if it involves a temporary socio-economic change (e.g., during construction or up to 3 years).
– Long term: an impact is considered long term if it involves a socio-economic change which is permanent or will be experienced over an extended period (e.g., over 5 years).

3.5.1.3 Spatial context

The spatial extent of an impact refers to the geographical rage in which something extent over which a change extends, and includes:

– Local: an impact is considered to have local spatial context if it involves a socio-economic change which will have an adverse or beneficial impact on the immediate surrounds and George Town.
– National: an impact is considered to have national spatial context if it involves a socio-economic change which will have an adverse or beneficial impact on the Cayman Islands.

3.5.2 Assess the significance

Potential social impacts were organised according to the socio-economic elements described in Section 3.5. An assessment of the identified socio-economic impacts was then undertaken to determine their likely level of 'significance' in accordance with Section 4 of the Terms of Reference. Significance was determined by considering the sensitivity of socio-economic receptors (individuals or social or economic groups), (Table 3.4), and the anticipated (most likely) magnitude of the impact if it were to occur (Table 3.5). The overall level of significance was determined by combining the sensitivity and magnitude criteria as shown in Table 3.6.

Table 3.4 Description of sensitivity

Sensitivity level	Description
Very low	Where the social area of influence is economically diverse and socio-economic indicators demonstrate an ability for the area to recover easily from the impact and natural, cultural and social functions are minimally affected.
Low	The socio-economic environment has minimal areas and levels of vulnerability and a high ability to absorb or adapt to change.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Sensitivity level	Description
Medium	The socio-economic environment has some vulnerabilities but retains some ability to absorb or adapt to change.
High	The socio-economic environment exhibits a number of vulnerabilities and/or little capacity to absorb or adapt to change.
Very high	The socio-economic environment exhibits multiple vulnerabilities, will be irreversibly changed, and it will have a significant impact on natural, cultural and social functions of the community, leading to a compromise to the way of life.

Table 3.5 Description of magnitude level

Magnitude level	Description
Very low	No discernible positive or negative changes caused by the impact. Change from the baseline remains within the range commonly experienced by receptors.
Low	Minor changes to the social environment, which are easily reversible over time; localised impact among a small group of impacted stakeholders.
Medium	Noticeable deterioration/improvement to something that people value highly, either lasting for an extensive time, or affecting a group of people.
High	Substantial deterioration/improvement to something that people value highly, either lasting for an indefinite time, or affecting many people in a widespread area.
Very high	There is irreplaceable impact to a highly valued community, social, infrastructure area or item of international significance and would lead to loss of license to operate.

Table 3.6 Significance rating

		Magnitude of Change				
		Very High	High	Medium	Low	Very Low
Sensitivity	Very High	Major (Significant)	Major (Significant)	Major (Significant)	Major (Significant)	Moderate (Possibly significant)
	High	Major (Significant)	Major (Significant)	Major (Significant)	Moderate (Possibly significant)	Minor (Not significant)
	Medium	Major (Significant)	Major (Significant)	Moderate (Possibly significant)	Minor (Not significant)	Negligible (Not significant)
	Low	Major (Significant)	Moderate (Possibly significant)	Minor (Not significant)	Negligible (Not significant)	Negligible (Not significant)
	Very Low	Moderate (Possibly significant)	Minor (Not significant)	Negligible (Not significant)	Negligible (Not significant)	Negligible (Not significant)

Source: ISWMS Terms of Reference (2021)

The risk rating then determines if mitigation or management actions are required to address the socio-economic impact, or enhance the socio-economic benefit.

This SEIA has assessed the potential socio-economic impacts and benefits that may occur as a result of construction of the project (Section 6) and operation of the project (Section 7).

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

3.6 Development of management measures

Following the identification of impacts, measures were developed to enhance the positive impacts of the Project and to avoid, mitigate or manage negative impacts (collectively referred to as 'management measures'). Management measures were developed based on the findings of:

– Stakeholder consultation
– The assessment of potential social impacts
– The knowledge of the SIA study team in developing and implementing management frameworks

Impact management measures are identified in Section 8 of this SIA.

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

4. Stakeholder consultation

This section presents a summary of key themes and issues relevant to this SEIA raised by stakeholders and community members during SEIA consultation. Chapter 5 of the EIA details the broader EIA engagement activities undertaken for the project.

4.1 SEIA consultation

Table 4.1 provides a summary of key themes and issues raised by stakeholders during SEIA consultation.

Table 4.1 Summary of key themes and issues

Topic	Description
Amenity impacts	– There are concerns about the potential amenity impacts including air quality and pollution, noise, and traffic and access from the new facility. – Some stakeholders raised concerns around the frequency of fires at the existing landfill and the associated decreased air quality particularly for those who live and work around the existing site. – Most stakeholders were supportive of the potential overall visual improvements of the project at the existing landfill site especially with regards to improved visual amenity for tourism. – General comments about the poor road infrastructure near the existing landfill site and impacts construction activities will have on the road quality. – Some stakeholders reported that odour is a current problem at the existing landfill site.
Environmental impacts	– There was overall support for better environmental outcomes from the closure of the existing facility and the capacity of the new facility. – There was interest among stakeholders in the new facility potentially providing power to the existing grid and consequently overall lower energy costs for local Caymanians. – Some stakeholders raised concerns around potential run-off pollutants ending up in the nearby bay and ocean which could impact marine wildlife and overall health of the marine ecosystem. – Additional waste generated after hurricanes and other bad weather is a key issue facing the islands. Some stakeholders questioned if the new facility will have the ability to accommodation this additional waste.
Hazards and safety	– There was interest from stakeholders around the new facility's ability to deal with chemical, hazardous, and biological waste. – Some stakeholders raised safety concerns of the existing landfill and were interested in the safety measures, management and mitigation methods for the new facility. – Existing health and safety legislation is currently lacking and is not enforced on the Islands.
Health and wellbeing	– Most stakeholders were interested in the health and wellbeing benefits and overall improvements to local residents from reduced air pollution and visual impacts.
Economic and businesses	– The nature-based tourism industry is an important part of the Cayman Islands which has increased in popularity over the last decade. – Some stakeholders raised queries as to who will operate the facilities once up and running.
Workforce and labour force	– There was keen interest in procurement and other business opportunities for local people, businesses and industries. – Rising cost of living expenses was a key barrier effecting the attraction and retention of new workers from overseas. – 'Green jobs' was raised as a potential employment opportunity to future proof the workforce and skills availability in the Cayman Islands. – Across the Cayman Islands there is a strong dependency on the financial and insurance service industry and tourism industry which both contribute significantly to the economy.

Topic	Description
	– Some stakeholders raised concerns about the lack of local labour force availability and increases in the foreign labour force which makes up a large portion of the tourism, financial services and construction industries. – There was interest among stakeholders about the potential long term employment opportunities during the operation of the new facility.
Skills and education development	– Some stakeholders indicated that there is a lack of local skills available particularly in the highly specialist/ technical fields or niche skills. – There was interest from stakeholders in potential skills development and local education and training opportunities for local Caymanians to either upskill or train in a new field to support the delivery of the new facility. – Some stakeholders mentioned opportunities to increase education and knowledge around litter and waste management practices across the Cayman Islands.
Housing and accommodation	– Housing availability and affordability is a key challenge across the Cayman Islands. Some stakeholders raised concerns around potential housing challenges and shortages from the arrival of overseas skilled migration.
Community	– There are a number of vulnerable people and people of lower socio-economic status who live around the existing landfill site. – Rapid population increase and overcrowding has put a strain on the existing infrastructure on the Islands including the existing landfill services and capacity and overall waste management. – Some stakeholders mentioned there exists scepticism from local community members around the existing recycling options available and where that recycled material gets used/ sent to after recycling. – The local community value, and take pride in, the natural environment.
Other	– There is a current shortfall in other waste management services available including haulage services, curb side pick up and recycling. – Some stakeholders raised questions about resource recovery store available at the landfill for items that can be reused or resold. Also noting that it would be good to have more of these available in each community to support the reuse of items. – There is current work being undertaken by the Government to ban single use plastics on the Islands.

5. Baseline conditions

The section establishes the socio-economic context for the SEIA study areas, against which potential impacts of the proposed ISWMS development can be identified and measured.

5.1 Project footprint and immediate surrounds

The existing George Town Land Fill (GTFL) site, also known locally as 'Mount Trashmore', is currently one of the most pressing environmental issues for the Island. The GTLF can be seen by local and visitors from across the island as well as offshore. Part of the existing landfill is currently undergoing capping and remediation.

As described in Chapter 3, the proposed ISWMS development encompasses 11.9 acres (4.8 hectares (ha)) of the existing GTLF site for the development of a new Residual Waste Landfill and Landfill Gas Facility, together with a 16.8 acres (6.8 ha) parcel of undeveloped land immediately south-west of this for the remainder of the ISWMS facilities.

The undeveloped parcel of the ISWMS Site is zoned Heavy Industrial (HI). This designation includes all of the activities proposed at the ISWMS Site: power generation, solid waste disposal and recycling. The proposed ISWMS activities are consistent with existing zoning designations and activities on the lands surrounding the proposed ISWMS development. The site is accessed via Seymour Drive.

The land usage surrounding the ISWMS site is summarised in Table 5.1 below.

Table 5.1 Description of land uses surrounding the ISWMS site

Direction	Land use description
North	The existing GTLF lies immediately north and east of the proposed ISWMS Site. North of the GTLF is a tidal drainage channel managed by Mosquito Research & Control Unit (MRCU) for mosquito control that connects with North Sound about 0.7 miles (1.23 kilometres (km)) to the east. The area immediately north of the drainage channel is the alignment of the under-construction Airport Connector Road (ACR) and further north lies a swathe of disturbed mangrove area. The under-construction Health City Hospital, Cayman International School and Camana Bay development are located within 0.5 mile (0.8 km) to the north of GTLF. The Cayman International School (CIS) is a private, college preparatory, co-educational school for students from two years old through to Grade 12. It provides American/International educational services for the dependents of the multi-national professionals living in Cayman. In 2021, there were 955 students enrolled at CIS[1]. The Camana Bay development is a mixed-use master-planned community consisting of a town centre with retail and commercial office space, a marina village and a collection of residential neighbourhoods.
East	The land east of the GTLF is owned by Cayman Water Authority and comprises four large former wastewater treatment lagoons that are used for sludge storage. South of the lagoons is the current wastewater treatment plant including some buildings and four smaller basins. Approximately 524 ft to 1049 ft (160 m to 320 m) east of the landfill site is land zoned for industrial use. This is mainly undeveloped or used for open storage. The Department of Environmental Health (DEH) collections depot (comprising several trailers for staff facilities and parking for staff and collection vehicles) is located on approximately one acre of land to the east of the wastewater treatment lagoons.
South	The southern boundary of the proposed ISWMS site is currently an area covered by mangroves, beyond which is industrial and commercial development. This land is occupied by a variety of businesses, including a concrete batching plant and a concrete block and paver stone manufacturer.
West	The Esterly Tibbetts Highway (the main arterial road to West Bay) lies immediately adjacent to the fence line forming the western boundary of the proposed ISWMS site.

Direction	Land use description
	The Lakeside residential development is located west of this Highway. This development comprises 12 three-storey residential apartments with car parking and leisure/landscape areas (including a small lake). The North Mound of the GTLF is visible from the easternmost lakeside buildings

5.2 Local and regional study area

5.2.1 Overview of the study area

The Cayman Islands are a British Overseas Territory located in the Caribbean Sea, approximately 257 kilometres (km) south of Cuba and 269 km north-west of Jamaica. The Cayman Islands is comprised of three islands: Grand Cayman, Cayman Brac and Little Cayman. In total, they encompass 263 square kilometres (km^2).

The project site is situated in the nation's capital of George Town, located on the western shore of Grand Cayman. The city covers approximately 29 km^2 and is one of six districts of the Cayman Islands.

Caymans natural resource base, including beaches, coral reefs and other marine resources is a main draw for the tourism industry, a second vital pillar of the nation's economy (CIG, 2019).

George Town is the economic, commercial, and governmental centre of the islands. It is the site of several of Grand Cayman's main tourism attractions, including Seven Mile Beach Popular and Stingray City, and hosts the majority of the Islands' hotels, resorts, and restaurants.

5.2.2 Demographic profile

5.2.2.1 Population

In 2021, George Town had a population of 34,921 persons, representing 49.1 percent of the Cayman Islands total population (Table 5.2). Between 2010 and 2020, the population of George Town increased by 24.3 percent at an average annual growth rate of 2.2 percent. This was slower than the annual growth rate recorded between the period between 1999 and 2010 (3.3 percent).

The overall population of the Cayman Islands was estimated at 71,105 persons in 2021. The population of the country increased by 29.2 percent between 2010 and 2021, however, decreasing from the 41.0 percent that was recorded between 1999 and 2010.

The population of the Cayman Islands was comprised of residents from 162 countries. The top countries of birth outside of the Cayman Islands were Jamacia (24.8 percent), Philippines (5.5 percent), UK (5.3 percent) and the USA (5.2 percent).

Table 5.2 Estimated population of local and regional study areas (1999, 2010, 2021)

Study area	1999	2010	2021	Percentage (percent) change		Annual percent change	
				'99 – '10	'10 – '21	'99 – '10	'10 – '20
George Town	20,626	28,089	34,921	36.2 percent	24.3 percent	3.3 percent	2.2 percent
Cayman Islands	39,020	55,036	71,105	41.0 percent	29.2 percent	3.7 percent	2.7 percent

Source: ESO, 2022

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

5.2.2.2 Age and sex profile

Previous census data indicated the median age of the Cayman Islands' population increased from 32.8 years in 1999 to 35 years in 2010 (ESO, 2011; p.19). The populations median age at the time of the 2021 census was 38 years for both males and females (ESO, 2022; p. 11).

Data from for the 2021 census (Table 5.3) shows there are proportionally more men than women in George Town at 51.7 percent and 48.2 percent, respectively. This ratio is similar at the national level with men comprising 50.6 percent and women comprising 49.3 percent of the total population.

Table 5.3 Sex profile of local and regional study areas (2021)

Area	Male	Female
Cayman Islands	50.6 percent	49.3 percent
George Town	51.7 percent	48.2 percent

Source: ESO, 2022

The Cayman Islands is characterised by an ageing population with an estimated 7.9 percent of the population aged 65 years and over at the 2021 census, compared to only 5.1 percent in 2010 (Table 5.4). This is consistent with the increasing age dependency ratio in the Cayman Islands, which was reported at 33.8 percent in 2020 compared to 30.8 percent in 2010 (ESO, 2021).

In contrast, the proportion of youth (0 to 14 years) decreased slightly from 18.1 percent in 2010 to 15.9 percent in 2021. The majority of the Cayman Islands population are persons in working age groups (75.5 percent), between the ages of 15 and 64 years.

Table 5.4 Population by age group, Cayman Islands (2010 and 2020)

Age group	2010		2021	
	Total	percent	Total	percent
0 -14 years	9,968	18.1 percent	11,315	15.9 percent
15 - 29 years	10,747	19.5 percent	12,251	17.2 percent
30 - 49 years	23,167	42.1 percent	27,291	38.4 percent
50 - 64 years	8,168	14.8 percent	14,130	19.9 percent
65 + years	2,832	5.1 percent	5,602	7.9 percent
Not stated	153	0.3 percent	515	0.7 percent

Source: ESO, 2022

5.2.2.3 Households

In 2021, there were a total of 29,699 households in the Cayman Islands. The 2021 census data shows that 6,939 households were added between 2010 and 2021, representing a 30.5 percent increase over that time (ESO, 2022; p. 50).

The average household size declined marginally to 2.39 persons per household in 2021. Except for George Town, which remained constant over the census period, all districts recorded marginal reductions. George Town accounts for 51.6 percent of households in the Cayman Islands (15,331 households). The average household size in George Town is 2.3, which is slightly lower than the national average of 2.4 persons per household.

5.2.2.4 Cultural diversity

In 2021, 88.8 percent of the total population (Caymanians and non-Caymanians) spoke English as the main language at home (or 95.5 percent for Caymanian and 81.0 percent for non-Caymanian). For non-Caymanians, Filipino was the

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

next most spoken language at home (8.0 percent) while for Caymanians, Spanish was the next most spoken language at home (3.2 percent) (ESO, 2022).

5.2.3 Employment and economy

5.2.3.1 Labour force and employment

In 2022, the Cayman Islands had a working age population of 69,383 people, with 57,582 of these within the labour force resulting in a labour force participation rate of 83.0 percent. Males (53.6 percent or 30,841 people) made up slightly more of the labour force compared to females (46.4 percent or 26,741 people). Of those employed, non-Caymanians made up 53.4 percent of the employed persons (ESO, 2023; p. 10).

There is also a strong foreign labour force within the Cayman Islands. Foreign workers have sought to take advantage of the relatively easy access to Caymanian employment market afforded by temporary work permits (Amit, 2001). As of January 2023, and estimated 34,067 people were recoded as having a work permit. Of these the top six nationalities on work permits included Jamaica (14,586 people or 42.8 percent), Philippines (5,284 people or 15.5 percent), UK (1,983 people or 5.8 percent), India (1,899 people or 5.5 percent), Honduras (1,234 people or 3.6 percent), and Canada (1,218 people or 3.6 percent) (Department of Workforce Opportunities & Residency Cayman, 2023).

The *Review of Employment Policy and Strategy in the Cayman Islands* (Cayman Islands Government, 2015) highlighted that the Caymanian population is unable to meet the existing labour demand, and it is not expected to meet this demand in the foreseeable future due to anticipated growth of the local population in relation to the anticipated growth of the local economy. During consultation, stakeholders confirmed this trend, noting that there is often not enough local labour to meet the demand of certain industries, with foreign labour comprising a large proportion of the of the tourism, financial services and construction industries.

5.2.3.2 Unemployment and underemployment

Of the labour force, there were 1,227 people unemployed within the Cayman Islands in 2022, resulting in an unemployment rate of 2.1 percent. The unemployed labour force mainly consisted of persons aged 25 to 34 years (421 persons), accounting for 34.3 percent of the total unemployed.

'Underemployment' is defined as 'Involuntary part-time' work, where workers who could (and would like to) be working for a full work week can find only part-time work. The underemployed accounted for 5.1 percent (4.9 percent male and 5.3 percent female) of the employed in 2022. Caymanians and Permanent Residents had above-average underemployment rates of 6.4 percent and 6.6 percent respectively, while non-Caymanians had a lower rate of 4.0 percent.

The *Review of Employment Policy and Strategy in the Cayman Islands* (Cayman Islands Government, 2015), highlights a number of barriers to employment amongst the local Caymanian population, including a lack of training and development, a lack of internet and transportation and poor housing.

5.2.3.3 Key sectors of employment

Within the Cayman Islands the top six industries accounted for 59.4 percent of the employed labour force. The largest employing industries in 2022 were construction (15.7 percent); wholesale and retail trade (12.8 percent); professional, scientific, and technical activities (9.2 percent); administrative and support service activities (7.3 percent); activities of households as employers (7.3 percent) and financial and insurance activities (7.1 percent) (ESO, 2023; p. 20).

Financial services

The financial services industry within the Cayman Islands employed 3,654 people during 2021, accounting for 8.2 percent of total employment within the country. In 2021, this industry was the fourth largest employer in the Cayman Islands. The financial services industry contributed $1,486 million worth of GDP to the Cayman Islands

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

economy in 2019 (or 30.4 percent of GDP). The Cayman Islands had a total of 111,568 registered companies in 2020, with 92,550 of these being identified as exempt companies (whose proposed activities are to be carried out mainly outside the islands (offshore)), with an additional 11,731 new companies being registered between 2019 and 2020 (ESO, 2021; p. 134-135).

Tourism

The Cayman Islands recorded 659,900 visitors in 2020, down significantly compared to the 2,333,700 visitors in 2019 as a result of the global pandemic. Pre-2020, the Cayman Islands recorded in excess of 2.1 million visitors annually since 2015, with the majority of visitors (78.5 percent of visitors) arriving to the island on cruise ships in 2019. For visitors arriving to the Cayman Islands by air, 83.3 percent of these were from the USA, with Canada accounting for 6.0 percent of air arrivals and Europe accounting for 4.8 percent. Air arrival visitors to the Cayman Islands spent an average of 6.09 days within the country during 2019, travelling in a party of 2.39 people and spending on average CI$201.70 per night. In contrast, cruise ship visitors were estimated to spend on average CI$94.90 per day within the country (ESO, 2021; p. 150 – 155). Consultation indicated that tourism numbers were beginning to return to pre-2020 levels.

The tourism industry has grown rapidly within the Cayman Islands. While the tourism industry is one of the largest industries on the islands it is dependent on a foreign workforce with Caymanians reluctant to seek employment in the industry (Amit, 2001).

5.2.3.4 Occupation of employment

The top five occupations, which collectively accounted for 79.1 percent of total employment, were professionals (18.8 percent); service and sales workers (17.0 percent); craft and related trades workers (16.5 percent); elementary occupations (14.2 percent), and technicians and associate professionals (12.6 percent) (ESO, 2023; p. 19).

5.2.3.5 Income

In 2021, 4,213 employed persons recorded annual earnings of between $14,400 - $19,199, which makes up 9.5 percent of employed persons. Within this income bracket women made up 59.5 percent and men made up 40.5 percent. The next highest annual earnings recorded was within the income bracket of $100,800 and over, which made up 8.8 percent of the total employed persons. Within this income bracket men made up 63.0 percent and women made up 37.1 percent.

Employed persons with annual earnings of between $19,200 - $23,999 were in the third highest bracket at 8.6 percent. Those with annual earnings between $24,000 - $28,799 were in the fourth highest income bracket at 8.1 percent of the total of employed persons. 1.0 percent of employed persons recorded annual earnings of $0 - $4,799. This income bracket represented the lowest percentage of employed persons.

5.2.3.6 Cost of living

The cost of living in the Cayman Islands is among the highest in the world. Recent estimates, estimate that the average monthly costs for a family of four is CI$,6,821 and CI$3,959 for a single person (Expatistan, 2023).

Increases in the Consumer Price Index (CPI) also indicate rising costs in consumer goods and services. Between 2020-21 CPI rose 3.3 percent (ESO, 2022).

Consultation indicated that increases in the cost of living across the Cayman Islands is a key barrier to people moving and staying on the Islands as well as finding affordable housing.

5.2.3.7 Regional output

As shown on Figure 5.1, the GDP of the Cayman Islands was CI$4.72 billion in 2021 (current prices). The financial and insurance services sector was the largest contributor in 2021 contributing $1.5 billion or 30.7 percent to GDP

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

followed by the professional, scientific and technical activities industry which contributed $0.7 billion or 15.2 percent to GDP (ESO, 2022).

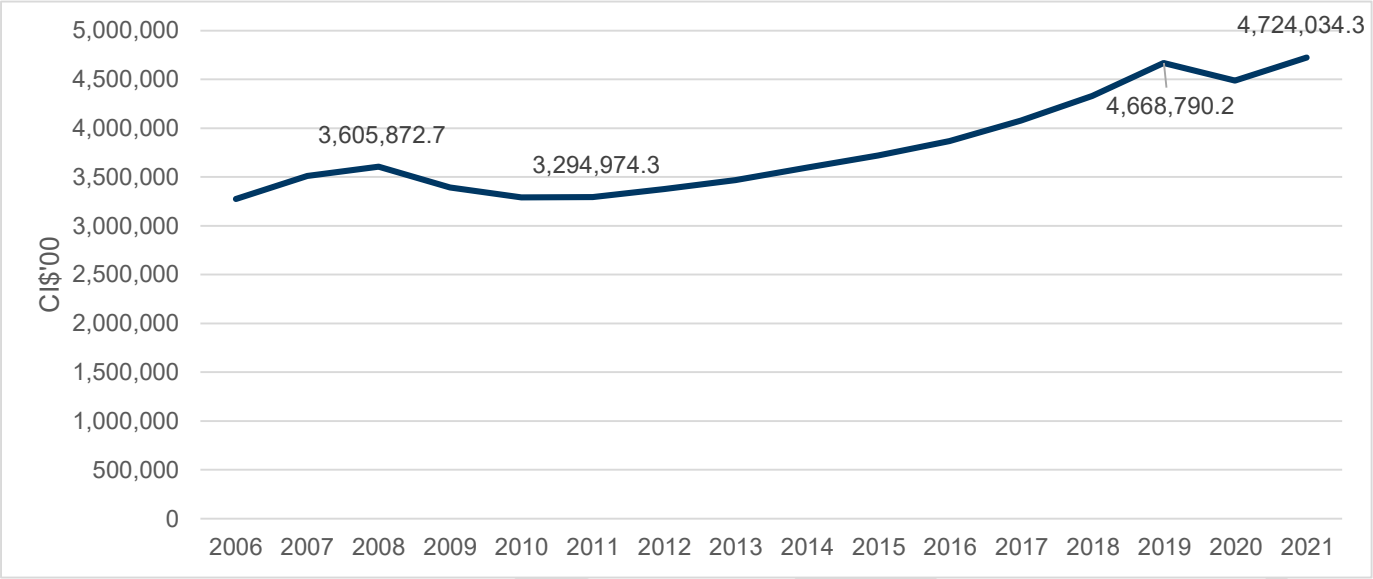

Figure 5.1 Cayman Islands GDP at Current Basic Prices 2006-2021

Source: ESO, 2022

5.2.4 Education

There are six universities and technical colleges located within the Cayman Islands. The University College of the Cayman Islands offers a number of programs and course and is the only public university on the Islands.

In 2021, 13.3 percent of those 15 years and older (both Caymanians and non-Caymanians) had attained technical/ vocational training. 8.8 percent of those 15 years and older (both Caymanians and non-Caymanians) had attained associate or equivalent level education and 30.3 percent had attained a bachelor's degree of higher.

When this is split into Caymanian and non-Caymanian subset, non-Caymanians have a higher rate of attainment of technical/ vocational training at 15.7 percent, compared to 11.0 percent of Caymanians. Attainment of a Bachelor's degree, Master's degree, Doctoral or equivalent education was higher for non-Caymanian's (36.2 percent) than Caymanian (24.3 percent). Attainment of associate level or equivalent education is higher for Caymanians at 10.5 percent than in non-Caymanians (7.0 percent).

Of the total school attendees in the Cayman Islands, the majority attend school in George Town.

5.2.5 Housing and accommodation

5.2.5.1 Tenure

Renting (furnished) is the most common type of tenure for dwellings among households in George Town (58.3 percent), followed by ownership with a mortgage (18.9 percent) (Table 5.5). These trends are similar for the national level. The high percentage of rentals points to the presence of a large immigrant population on contracts of employment, and who need to rent accommodation during their stay in the Cayman Islands (Kairi Consultants Ltd, 2008).

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. Table 5.5 Housing tenure

Housing tenure type	George Town		Cayman Islands	
	Number	percent	Number	percent
Owned with a mortgage	2,903	18.9 percent	6,787	22.9 percent
Owned without a mortgage	2,413	15.7 percent	6,052	20.4 percent
Rented - Furnished	8,943	58.3 percent	14,668	49.4 percent
Rented - Unfurnished	348	2.3 percent	568	1.9 percent
Subsidised Rent	48	0.3 percent	128	0.4 percent
Rent Free	278	1.8 percent	673	2.3 percent
Other	40	0.3 percent	113	0.4 percent
Not stated	356	2.3 percent	711	2.4 percent
Total	15,331	-	29,699	-

Source: ESO, 2022; p. 279

5.2.5.2 Median weekly rent

The rental market in the Cayman Islands has seen consistent growth over the last decade from 2010 to 2020. While COVID-19 has impacted rental rates in response to decrease in tourism and associated industry workers relocating, rental prices have returned to the decade long trend (IRG International, 2021). During consultation, stakeholders noted that the cost of living, and in particular, high housing costs is an issue in Cayman.

The average rental prices in Georgetown and across Grand Cayman are summarised in Table 5.6:

Table 5.6 Average rental price by location and accommodation type 2023

Area	1 Bedroom	2 Bedroom	3 Bedroom
West Bay	$900-1,500	$1,500-4,000	$2,500-3,200
Seven Mile Beach	$2,000-2,500	$3,500-5,500	$5,000+
Seven Mile Corridor	$2,000-2,500	$3,000-5,500	$5,000+
George Town	$1,100-2,100	$2,000-2,500	$4,000+
South Sound	$1,800-2,750	$2,000-3,000	$3,200+
Prospect/Savannah	$1,200-2,000	$1,750-2,500	$3,000+
Bodden Town	$950-1,500	$1,200-2,500	$2,500+

Source: https://caymanresident.com/housing/rentals/renting-a-property (reported 2023)

5.2.5.3 Median house price

There is a large disparity of house prices in the Cayman Islands and relatively small number of properties in the market. As such, reporting on house prices is often categorised by housing type, to attempt like-for-like market trend analysis. Sales data reported for villas in George Town shows that this area of the Cayman Islands has seen the some of the greatest surges in property prices. The average price per unit for a villa in George Town in 2010 was CI$383,000, increasing to CI$655,464 in 2018 and CI$918,952 in 2020 (Whittaker, 2021).

This trend is reflected at the national level, where an independent review of government data, found that open market property values steadily increased over the 2013 and 2019 period (Charterland Ltd, 2019). While COVID-19 related constraints brought challenges to this trend in early 2020, data from 2021 show property prices and transfer rates

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

returning to pre-COVID-19 trends (Lands and Survey Department, 2021). The average house price in 2020 was CI$700,000 (Whittaker, 2021).

As mentioned in Section 5.2.3.6 the cost of living in the Cayman Islands is one of the highest in the world and increasing. Consultation supported this and indicated that an increase in cost of living across the Cayman Islands as a barrier to attracting and retaining skilled workforce.

5.2.5.4 Short term accommodation

Short-term rental accommodation has become increasingly popular on the Islands as it has become highly desirable for tourist visiting the Islands. In May 2023, there were approximately 226 short-term rental accommodation listings available on Airbnb on Grand Cayman Island. The short-term rental accommodation available on the Islands plays an important role in supporting the tourism industry and wider economy. Under the Tourism Law (1995), short-term rental accommodation must be operated by a licenced provider in the Cayman Islands. During consultation, stakeholders noted that there can be issues with the availability and affordability of available housing, particularly during peak tourism seasons.

5.2.6 Natural environment

The natural environment of the Cayman Islands is rich in biodiversity which attracts visitors from overseas and boost environmental and nature-based tourism businesses as well as the overall economy on the Islands.

Currently, the National Trust protects approximately 6 percent of terrestrial areas. These protected reserves are designed to conserve wilderness representing areas of high biological diversity and significance. These areas of high importance include Salina Reserve, Collier's Wilderness Reserve, Governor Michael Gore's Bird Sanctuary, Mastic Reserve, and Malportas Pond Bird Sanctuary (National Trust, 2022). Aquatic and coastal areas around the Islands are also of importance with several important coral reefs, sea grasses and mangrove forests providing essential nutrients and habitat to fish colonies and other sea life (DOE, 2023).

There are also several terrestrial areas protected under the National Conservation Law in Grand Cayman, including the Western Mangrove Cays which is located approximately 2km north-east from the project site (National Conservation Council of the Cayman Islands, 2022).

Consultation undertaken for this SEIA indicated residents and tourist value the natural environment of the Cayman Islands. As mentioned earlier nature-based tourism is a significant draw for tourism on the islands.

5.2.7 Community health and wellbeing

5.2.7.1 Community identity and values

The local community have a strong sense of community and pride in local heritage. They also value and have a deep respect for the environment. The Cayman Islands have a rich and unique cultural heritage blending Caribbean and European style and influence (Destination Cayman Islands, 2021).

Consultation with stakeholders noted that the local residents of the Cayman Islands highly value the natural environment including the terrestrial and marine environments where there are key unique flora and fauna. The local community also value the protection of these natural environments.

5.2.7.2 Health

The Cayman Islands enjoys a relatively high standard of living, as reflected in an annual per capita gross national income of US$61,880 in 2021 (12th in the world) (World Bank, 2023). The high standard of living, together with the high level of general and specialised medical care universally available in the Cayman Islands have contributed to the relatively good health of the population (Kairi Consultants Ltd, 2008).

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

The ESO's 2020 Annual Compendium of Statistics recorded several improvements in health status and outcomes for the Cayman Islands population over recent years, including:

– Between 2005 and 2020 the general mortality rate fell from 3.8 deaths per 1,000 population to 3.3.
– Between 2002 and 2020 the infant mortality rate decreased from 13.7 deaths per 1,000 live births to 3.6.

Alongside these improvements, the Cayman Islands Government has recognised an important concern regarding the health status of the Cayman population relates to the gradual shift in disease patterns over the years, with chronic/lifestyle non-communicable diseases becoming more prevalent than communicable disease (Ministry of Health, 2012). Mortality data for 2008 indicates that the leading causes of death in the Cayman Islanders were cardiovascular disease, heart disease, cancer, and respiratory diseases (Ministry of Health, 2012).

5.2.7.3 Crime and security

Data from the Royal *Cayman Islands Police Service* (RCIPS), which showed in 2021 (RCIPS, 2021):

– There were 3,696 total recorded crimes, accounting for 11 percent of all incidents or calls for service. There have been 140 more crimes recorded in 2021 compared to 2020 equating to an increase of 3.9 percent.
– There were 56 crimes per 1,000 population in 2021, compared to 51 crimes in 2020.
– There was a total of 131 burglaries in 2021, a reduction of 26 compared to 2020, equating to a 16.6 percent year on year reduction.
– There was a slight decrease in the number of recorded offences involving domestic abuse, from 469 in 2020 to 406 in 2021. However, this reportedly decrease goes against the trend of year-on-year increases seen in previous years.

Consultation supported the finding that the Cayman Islands is a relatively safe place to live and visit. Car accidents and speeding were the most common type of incidents reported on the islands leading to the Cayman Islands having one of the highest road incidents in the world per capita. Other crimes include those involving drugs and alcohol.

5.2.8 Access and connectivity

The Islands can be accessed via plane or ship. Owen Roberts International Airport which is the main access point for international visitors is located in George Town on Grand Cayman Island. There are direct flights to 18 cities across the USA including New York City, Los Angles, Miami, and Denver. There are also direct flights from Panama, Jamaica, Cuba, and Honduras. There are four cruise ship offshore anchor points located off Grand Cayman Island. Access to the Island from cruise ships is via two major port entries located at Grand Cayman and Cayman Brac.

When on the Islands, car travel is the most common and best way to get around. An existing bus service exists within the study area. According to the Public Transport Unit within the Cayman Islands Government, bus 5A travels along North South Road passing the south end of Seymour Road. Seymour Road is the main access road to the existing landfill site. Seymour Road connects with North Sound Road and to the main access roads of Esterly Tibbetts Highway and Godfrey Nixon Way, which connects various parts of the Island (APEC, 2023). Other transport options include taxi's, walking, bicycle and rideshare options.

5.2.9 Access to services and infrastructure

5.2.9.1 Health infrastructure

Cayman Islands is serviced by a number of hospitals and health care services with three fully equipped hospitals in Grand Cayman, including, Cayman Islands Hospital, Doctors Hospital, and Health City Cayman Islands.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

The local study area is serviced by a mix of public and private health care services, notably:

– The 127-beds Cayman Islands Hospital is the principal health care facility of the country, providing 24-hour full service medical services (HSA, 2023). It is located on Smith Road, George Town approximately 4km from the project site and is operated by the Health Services Authority (HSA) of the Cayman Islands.
– The George Town District Health Centre, also operated by the HSA, also provides health services including physicians, including general physicians and mental health support services (HSA, 2021b). The Clinic is located at the Cayman Islands Hospital.
– Doctors Express is located in George Town and offers urgent care, family medicine, a pharmacy and other wellness services (Cayman Islands Urgent Care, 2021).
– Health City Cayman Islands is a tertiary care medical centre and hospital in Grand Cayman which opened in 2021 and offers a number of medical, surgical and diagnostic services (Health City Cayman Islands, 2023).
– The independently owned and operated Doctor's Hospital is located on Walkers Road in George Town, approximately 4.5km from the project site. It is an eighteen-bed, medical/surgical hospital (Cayman Health, 2021).

George Town is also serviced by a number of smaller, private health care clinics, general practitioners and pharmacies.

With respect to the capacity of these facilities, there are 4.7 doctors per 1,000 population in the country, representing a decrease from 5.5 in 2015 (ESO, 2021).

5.2.9.2 Police service

The Cayman Islands is serviced by the RCIPS. RCIPS has seven police stations and approximately 400 officers and support staff and 50 coast guards (RCIPS, 2021). The George Town Police Station, the main headquarters, is located on Elgin Street approximately 4km from the project site.

Consultation identified that the Police service do support the fire department in incident response and management as needed.

5.2.9.3 Fire service

The Cayman Islands Fire Service (CIFS) provides firefighting and rescue services nation-wide and is operational 24 hours a day 7 days a week. CIFS has approximately 153 staff members who work rotating shifts. The George Town fire station is located on Owen Roberts Drive, approximately 4km from the project site.

Consultation indicated that the Fire service currently attend to all fire related matters including aviation, education, residential, commercial, hazardous, and search and rescue. The Fire service also attend to fires at the existing landfill site on a regular basis. They also conduct annual inspections of the existing landfill including fire breaks around the landfill site.

5.3 Key findings

The key findings of the socio-economic baseline are summarised below:

– The population of George Town and the Cayman Islands has grown considerably over the last decade.
– There is a high migrant population in the Cayman Islands with a high proportion of people arriving from Jamacia, the Philippines, the UK, and USA. This is also reflected in the high foreign labour market and temporary workers permits.
– Along with the high foreign labour force there was high labour force participation. Males made up slightly more of the labour force compared to females.
– Unemployment across the Cayman Island was low at an estimate 2.2 percent in 2022. The majority of the unemployed labour force consisted of persons aged 25-34 years.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

- The construction industry was the largest employing industry in the Cayman Islands by total labour force making up over 15 percent of the total labour force.
- The financial services industry was the fourth largest industry by people employment and the largest industry by economic value contributing $1.5 billion to the GDP of the country.
- Tourism is a key industry on the Islands with over 2.1 million people visiting the Islands each year. The tourism industry also employs a significant proportion of the foreign labour market.
- Renting is the most common type of tenure across the Cayman Islands. Over the last decade the rental market has seen consistent growth with the average rental price for a 2-bedroom apartment between CI$2,000 and CI$2,500 per month. High rental prices and overall cost of living is seen as a barrier to housing affordability and attracting and retaining people.
- The natural environment of the Cayman Islands is highly valued and protected by the local community. The natural environment is also a key tourist attraction to the islands with a number of businesses in the nature-based tourism industry.

DRAFT

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

6. Impact assessment – construction

This section assesses the socio-economic impacts associated with the construction of the project. The sensitivity and magnitude have been determined in accordance with the methodology outlined in Section 3.5. The significance rating shown in Section 3.5.2 has been applied to each social impact based on the outcome of this assessment.

Table 6.1 Socio-economic impact assessment – construction

Impact summary	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
Population					
Population and demographic change from construction workforce	During construction, the workforce is estimated to be 300 employees over the duration of the three-year construction timeframe. As detailed within the *Works Delivery Plan* (Regen, 2023), there is aspiration for up to 100 personnel to be local Caymanian residents as employees or subcontractors. The project will prioritise the sourcing of construction personnel from the Cayman Islands, however, for the remaining workforce, and where workers are unable to be sourced from within the country, personnel may be engaged from elsewhere, including from other surrounding Caribbean islands and overseas. On this basis, project construction would contribute to a temporary population increase in Cayman. Given that the existing high tourism and non-resident worker populations is part of community composition in Cayman, a temporary increase in the non-resident population may not be highly noticed. Given the typical nature of construction workforce, it is also anticipated that the additional temporary population would be a predominantly single male population.	**Beneficial / Adverse** **Short term** **National**	**Low**	**Medium**	**Minor (neutral)**
Employment and economy					
Increase in direct local employment during construction.	The project's construction phase will create direct employment for approximately 300 FTE workers over the three-year construction period (on average 100 FTE per year), and for 15 months the number will exceed 250 people. This would provide employment opportunities for residents in Cayman, in particular those skilled in construction, engineering, project management and administration, potentially increasing the level of employment in the region. Stakeholders consultation indicated the potential of the project to have positive impact on the regional economy through direct employment opportunities was a key benefit.	**Beneficial** **Short term** **National**	**Low**	**Medium**	**Minor (beneficial)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Impact summary	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
	As detailed within the *Works Delivery Plan* (Regen, 2023), up to 100 individuals are proposed be local Caymanian residents engaged as employees or subcontractors (and for 16 months the percentage of local Caymanians will exceed 30 percent) during the construction period. Based on the number of people employed within the construction industry, this would amount to 1.5 percent of the total construction workforce currently within the Cayman Islands. Notwithstanding this, during consultation, stakeholders noted that there is often not enough local labour to meet the demand of certain industries, with foreign labour comprising a large portion of the construction industry.				
Increased training opportunities	The project's construction phase will provide opportunities to enhance skills and capacity of employees in the local and regional study areas through the proposed apprenticeships, traineeships and work experience opportunities throughout the works period, as identified in the *Works Delivery Plan* (Regen, 2023). Through the SEIA consultation it was understood that there is a strong interest in the potential for the project to create employment and skills development opportunities for the local population, however understanding these training requirements ahead of time is critical in allowing time for trade colleges and vocational education providers to upskill the existing workforce. Project training and development opportunities would provide particular benefit for young people and new entrants to the workforce who experience high levels of disadvantage and employment inequity in the regional study area.	**Beneficial** **Long term** **National**	**Medium**	**Medium**	**Moderate (beneficial)**
Increased competition for workers in local and regional labour market	During consultation, stakeholders noted that there are often labour challenges amongst local workforces for specialist roles, with many industries being supplemented by a foreign workforce. Consequently, there is potential for the project to draw local workers from existing jobs, potentially creating competition for labour for particular skills, particularly in the construction industry. This may result in increased skilled labour shortages for periods of the construction phase. The attraction of a construction workforce from existing businesses and industries in the region may contribute to competition for labour in the regional study area. This may lead to temporary labour shortfalls and increased cost of labour for other construction work, particularly if other projects are constructed during the same period.	**Adverse** **Short term** **National**	**Medium**	**Medium**	**Moderate (adverse)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Impact summary	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
Procurement opportunities for local businesses and the purchase of goods and services during construction	As noted in the *Works Delivery Plan* (Regen, 2023) the project will provide procurement opportunities for eligible regional businesses to provide construction materials and services (including civil works, construction and transportation), which would lead to increased revenue and business growth for those engaged and contribute to the regional economy. Consultation for the SEIA noted that there is capacity amongst local businesses to support the construction of the project.	**Beneficial** **Short term** **National**	**Low**	**Medium**	**Minor (beneficial)**
	During the construction period, the project will provide local spend at Cayman businesses through the provision of goods and services to support construction activities, including, but not limited to construction materials, uniforms, catering and accommodation. An increase in local spend opportunities would lead to increased revenue and business growth for those businesses.	**Beneficial** **Short term** **National**	**Low**	**Medium**	**Minor (beneficial)**
Indirect employment through procurement opportunities	The procurement of local and regional goods and services to support construction and operation of the project would indirectly generate employment opportunities for residents of the region.	**Beneficial** **Short term** **National**	**Low**	**Low**	**Negligible (beneficial)**
Increased in local trade associated with expenditure of wages	Local food and retail businesses in George Town would benefit economically from increased food and beverage trade as a result of patronage by the construction personnel working on the project site. Local businesses, including accommodation providers, and food and beverage providers may also benefit from short term foreign workers during the construction phase, as they would need to be accommodated nearby.	**Beneficial** **Short term** **National**	**Low**	**Medium**	**Minor (beneficial)**
Services and infrastructure					
Increased demand for housing and accommodation access	During construction, an influx non-resident workers may result in an increased demand on short term housing and accommodation in Cayman. During consultation, stakeholders noted that there existing pressures relating to the availability and affordability of housing and accommodation in Cayman, particularly during peak tourism seasons. Housing requirements during construction may result in reduced availability of rentals and short-term accommodation facilities.	**Adverse** **Short term** **National**	**Low**	**Low**	**Negligible (adverse)**
	Tourism is a major industry contributing to the Cayman Island economy. Increased pressure on short term accommodation, over the construction period, may have some impact on short-term accommodation availability for the tourism industry.	**Adverse** **Short term** **National**	**Very low**	**Low**	**Negligible (adverse)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Impact summary	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
Increased demand for community facilities and services.	The non-resident construction workforce may increase demand on local and regional community facilities and services, such health services. As identified in Section 5.2.9.1, there are a number of health services in Cayman, including the Cayman Islands Hospital and George Town District Health Centre. On this basis, it is anticipated that available services can absorb an increase in demand and therefore unlikely to impede of local community' s access to health services.	**Adverse** **Short term** **National**	**Very low**	**Low**	**Negligible (adverse)**
Increased demand on emergency services	There may also be demand for assistance from fire services in relation to fire planning / prevention to protect project infrastructure. During consultation, it was noted that emergency services are frequently required at the existing landfill site to respond to fires occur at the site. Increased construction activity in addition to an increase in population associated with the construction activity may result in increased demand for emergency services, particularly for the Cayman Island Fire Service.	**Adverse** **Short term** **National**	**Medium**	**Low**	**Minor (adverse)**
Perceived impacts to community safety and community cohesion	Research indicates a common concern raised by communities during the planning for major infrastructure projects relates to the 'influx' of non-local workers ('outsiders') and the perceived potential for an increase in anti-social behaviour, crime and overall reduction in community cohesion, particularly in small communities with limited exposure to development (Scott et al., 2011). The construction workforce (approximately 300 FTE workers over the three-year construction period) would include a proportion of non-resident workers. In the event that the majority of construction workers are from outside of the regional study area, there is potential that the occurrence of or any perceived anti-social behaviour could be attributed to the presence of construction workers and result in feelings of anxiety and distrust towards project workers by members of the local community.	**Adverse** **Short term** **National**	**Medium**	**Low**	**Minor (adverse)**
Changes in perception of personal safety	Presence of male dominated workforce during construction in George Town may contribute to concerns about community safety within Cayman particularly as the workforce would be non-local to Cayman. The presence of a non-local construction workforce may also concern some residents regarding reduction in feelings of community cohesion. However, given the high proportion of foreign workers currently in Cayman (Section 5.2.3.1), it is anticipated that residents are likely to adapt to an increase to the existing non-residential workforce.	**Adverse** **Short term** **National**	**Medium**	**Low**	**Minor (adverse)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Impact summary	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
Mental health of non-resident workers	Non-resident construction workforce may be at greater risk of mental health and wellbeing impacts. Isolation and loneliness has been found to contribute to feelings of decreased mental health for non-resident construction workforce.	**Adverse** **Short term** **National**	**Very low**	**Low**	**Negligible (adverse)**
Environmental quality and natural resources					
Increased noise, vibration and dust levels due to construction activities	Construction activities would generate noise, vibration and dust during standard work hours. This would involve the use of noise generating equipment, operation and movement of heavy machinery (such as dozers, graders, front end loaders, excavators, trucks and scrapers) and construction traffic. Most noise would be intermittent or sporadic throughout the construction period. Increased construction noise during the daytime may disturb day-to-day activities for affected residents, and impact their quality of life. This could include the need to close windows whilst indoors, or spending less time outdoors engaging in recreational activities or relaxation. Increased noise could disturb activities such as conversations, watching television, or listening to music or the radio. The *Noise and Vibration Assessment* (GHD, 2023) found that the project has the potential to produce noise emissions in the vicinity of the project above the documented baseline limits. These changes would be experienced for nearby sensitive receptors including nearby residential areas, residents along haulage routes, the nearby school and nearby hospital. The *Noise and Vibration Assessment* (GHD, 2023) has deemed that construction vibration impacts are 'insignificant' for all receptors with magnitude of change of "very low".	**Adverse** **Short term** **Local**	**Medium**	**Low**	**Minor (adverse)**
	The *Air Quality Impact Assessment* (GHD, 2023) found that some construction activities would have the potential to generate dust which would be experienced by residences and businesses close to the construction area, and at some residences along haulage routes. Increases in dust may lead some residents and businesses to alter their way of life, such as closing windows whilst indoors, spending less time outside, or spending additional time cleaning indoor and outdoor surfaces. The *Air Quality Impact Assessment* (GHD, 2023) has deemed that there are negligible dust effects likely to occur due to the construction activities and will be managed through the implementation of appropriate mitigation plans.	**Adverse** **Short term** **Local**	**Low**	**Low**	**Low (adverse)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Impact summary	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
Changes to visual amenity and sense of place	During consultation, stakeholders noted that the visual amenity and the natural environment is highly valued by residents and tourists of the Cayman Islands (Section 5.2.6). Additionally, stakeholders noted that the current landfill operations considerably reduce the visual amenity, particularly for surrounding residents, residents in high-rise apartment buildings, tourists using main roads, incoming cruise ships off Seven Mile Beach. The *Seascape and Landscape Visual Considerations Report* (GHD, 2023) found that there may be direct and indirect landscape effects upon the surrounding landscape/townscape/seascape character of areas during construction of the project (for those visual receivers/viewpoints with views to the project site). This would include the presence of construction machinery and infrastructure, construction workers, and views of construction vehicles along haulage routes. Changes to visual surroundings may impact residents' sense of pride in their local area, and reduce enjoyment of outdoor areas, or views from some windows and yards. Views of construction activities would have the potential to impact properties close to the project site in surrounding residential settlements and properties in high-rise residential properties on Seven Mile Beach. These residents are likely to be sensitive to these changes due to the value that is placed on the character of the area (Section 5.2.6), and the existing visual amenity impacts of the current landfill operation (Section 0). Visual impacts would be limited to the duration of the construction period, and most residents are expected to adapt to these changes.	**Adverse** **Short term** **National**	**Medium**	**Low**	**Minor (adverse)**
	The *Seascape and Landscape Visual Considerations Report* (GHD, 2023) identified that construction activities may be visual from high-rise residential properties on Seven Mile Beach, the National Gallery of the Caymans Island and Cruise Liners anchored off Seven Mile Beach, which are key areas for tourists. This would include the presence of construction machinery and infrastructure, construction workers, and views of construction vehicles along haulage routes. Tourists may be to be sensitive to these changes due to the value that is placed on the character of the area (Section 5.2.6). Visual impacts would be limited to the duration of the construction period, and most tourists are expected to adapt to these changes, as construction sites are a commonly occurring urban views.	**Adverse** **Short term** **National**	**Medium**	**Low**	**Minor (adverse)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Impact summary	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
Combined amenity impacts	Residents and businesses located adjacent to the project site and along construction haulage routes would have the potential to experience combined impacts during construction due to noise, dust and visual changes. Residents in the area would be sensitive to these changes, however as the site is located on the site of the existing landfill, it is not expected that residents will be able to adapt to these changes. Some residents may be more vulnerable, and there is potential for impacts to overall wellbeing for some.	**Adverse** **Short term** **National**	**Medium**	**Low**	**Minor (adverse)**
Access and connectivity					
Reduced traffic safety / increased risk of traffic accidents due to construction traffic	During construction, the *Traffic Statement* (APEC, 2023) anticipates that of the 300 staff, 150 additional vehicles would be added to the traffic along North Sound Road & Seymour Road during the peak periods, across the 3- year construction period. In addition to this, it is expected that there will be approximately 37 heavy vehicles will travel to and from the ISWMS site during the construction stage of the project. During consultation, stakeholders noted that along these roads there are existing traffic issues associated with long travel time during peak hours as well as a high number of traffic accidents. An increase in light and heavy vehicles on major roads may result in actual or perceived reductions in road safety for road users.	**Adverse** **Short term** **Local**	**Medium**	**Low**	**Minor (adverse)**
Increased travel times and inconvenience for local road users	Increased time spent travelling may cause delays in getting home, to work, or other commitments. This may be inconvenient for some road users and cause frustration.	**Adverse** **Short term** **Local**	**Low**	**Low**	**Low (adverse)**
Damage to roads as a result of construction traffic	The presence of construction traffic on local roads in Cayman, and in particular, in George Town, may result in damage to roads and potentially lead to increased travel time for commuters, increase the chances of damages to commuter vehicles and reduced road safety.	**Adverse** **Short term** **Local**	**Low**	**Low**	**Low (adverse)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

7. Impact assessment – operation

This section assesses the socio-economic impacts associated with the operation phase of the project. The sensitivity and magnitude have been determined in accordance with the methodology outlined in Section 3.5. The significance rating shown in Section 3.5.2 has been applied to each social impact based on the outcome of this assessment.

Table 7.1 Socio-economic impacts – operation

Impact category	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
Population					
Population and demographic change from operational workforce	As detailed within the *Works Delivery Plan* (Regen, 2023), the project is expected to require an operational workforce of 70 FTE workers per year. The project will prioritise the sourcing of operational personnel from the Cayman Islands, however, where workers are unable to be sourced from within the country, personnel may be engaged from elsewhere, including from other surrounding Caribbean islands and overseas. There is currently low levels of unemployment (Section 5.2.3.2) and a high proportion of foreign workers in Cayman, with stakeholders (during SEIA consultation) noting a number of industries are supplemented by non-resident workers, particularly specialist roles (Section 5.2.3.1). On this basis, it is likely that a proportion of the operational workforce may be sourced from overseas, requiring relocation to Cayman Islands, which is likely to result in a direct increase in the permanent resident population of Cayman.	**Beneficial / Adverse** **Long term** **National**	**Low**	**Medium**	**Minor (neutral)**
Employment and economy					
Increase in local employment during operation.	As detailed within the *Works Delivery Plan* (Regen, 2023), the project is expected to require an operational workforce of 70 FTE workers per year. These would be new roles and be predominantly skilled positions associated with the operation of the ERF and resource recovery facilities. This would provide employment opportunities for residents in the local and regional area, potentially increasing the level of employment in the region. However, there is low unemployment rates in Cayman (Section 5.2.3.2) with stakeholders (during SEIA consultation) noting that there is often not enough local labour to meet the demand of certain industries, with foreign labour supplementing a number of industries, and in particular, skilled roles (Section 5.2.3.1).	**Beneficial** **Long term** **National**	**Low**	**Low**	**Negligible (beneficial)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Impact category	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
	On this basis, operational-related local employment opportunities are likely to be limited to a small number of people, however, would be long-term in nature and sustain local employment opportunities.				
Contribution to the regional economy through procurement of goods and services, employment, and supporting growth of the renewable energy industry.	During operation, there would be opportunities for businesses in Cayman to supply goods and services to the ERF. This includes opportunities to service operations such as transport and logistics (e.g., waste haulage companies). The project also has the potential to generate new businesses to support its operations in Cayman as ERF technology is a new industry for the region.	**Beneficial** **Long term** **National**	**Medium**	**Medium**	**Moderate (beneficial)**
	During operation, the project will contribute to the regional economy through: – The sale of electricity from the ERF to the Caribbean Utility Company (CUC) – The Green Waste Processing Facility which will receive and process yard waste and will store the resulting compost and mulch products for onward resale into the Cayman marketplace – The Construction and Demolition Waste Processing Facility which will allow for the recycling, recovery and diversion of construction and demolition wastes which can be repurposed will be re-sold into the market These components of the project will contribute to the growth of the region's renewable energy and waste management industries.	**Beneficial** **Long term** **National**	**Medium**	**Medium**	**Moderate (beneficial)**
Opportunity to support local businesses through improvements in waste management	During operation, the waste management facilities, including the Construction and Demolition Waste Processing Facility and Green Waste Processing Facility will receive materials which includes yard materials, construction waste and demolition waste. Businesses such as construction and landscaping companies may benefit from appropriate facilities to manage their waste, assisting in their waste management process. This may improve processes and efficiency of waste management, which is likely to be positively received by local businesses.	**Beneficial** **Long term** **National**	**Low**	**Low**	**Negligible (beneficial)**
Opportunity for economic diversification	Operation of the project would contribute to economic diversification of the Cayman Island economy through the production of green electricity, the operation of new waste management technology and through the recovery and repurposing of resources. Diversification of the economy was noted as a key benefit of the project by stakeholders.	**Beneficial** **Long term** **National**	**Medium**	**Medium**	**Moderate (beneficial)**

Impact category	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
Opportunity for the project to support the growth of the tourism industry	Stakeholders consulted for the SEIA noted that within the tourism industry, there is an aspiration for more sustainable waste management practices.. Improvements in waste management practices, including the transition from the existing landfill site, may improve Cayman's tourism offering by allowing expansion the nature-based tourism market and to promote sustainable tourism practices. The tourism industry, including operators and business owners, are likely to be welcoming of improvements to waste management.	**Beneficial** **Long term** **National**	**Low**	**Low**	**Negligible (beneficial)**
Increased competition for workers in local and regional labour market	As discussed in Section 5.2.3.2, there is low unemployment rates in Cayman. Consequently, due to operational workforce requirements there may be potential for the project to draw workers from existing jobs, potentially creating competition for labour for particular skillsets. However, during consultation, stakeholders noted that there is often not enough local labour to meet the demand of certain industries and operational roles are likely to require specialist skills which may not be available in the local workforce. This may require outsourcing employment to non-resident workers which would reduce pressure on the local labour market.	**Adverse** **Long term** **National**	**Low**	**Low**	**Negligible (adverse)**
Increased capacity of the local workforce	During consultation, stakeholders identified that education and training associated with upskilling the workforce is a potential key benefit that could arise during operation of the project. Training opportunities would benefit residents of Cayman by building capacity and skills of the workforce, with stakeholders citing potential opportunities as including apprenticeships, traineeships, upskilling and linkages with existing training providers in the region.	**Positive** **Long term** **National**	**Medium**	**Medium**	**Moderate (beneficial)**
Services and infrastructure					
Increased demand for housing and accommodation	During operation, there may be non-residential workers being employed and subsequently permanently relocating to Cayman. An increase in non-resident operational workers may result in an increased demand on housing in Cayman. During consultation, stakeholders noted that there is existing demand on affordability and availability of housing and accommodation in Cayman, particularly during peak tourism seasons. Housing requirements during operation may result in reduced availability of long-term rentals.	**Adverse** **Long term** **National**	**Low**	**Low**	**Negligible (adverse)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Impact category	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
Increased demand for community facilities and services.	An increase in the permanent population of Cayman during operation may increase demand on local services and facilities, such as health services. As identified in Section 5.2.9.1, there are a number of health services in Cayman, including the Cayman Islands Hospital and George Town District Health Centre. The number of non-resident workers required for operation of the project is likely to be small, generating limited additional demand for community infrastructure. Community infrastructure is likely to cope with this additional demand.	**Adverse** **Long term** **National**	**Low**	**Low**	**Negligible (adverse)**
Increased demand on emergency services	There may also be demand for assistance from fire services in relation to fire planning / prevention to protect project infrastructure. During consultation, it was noted that emergency services are frequently required at the existing landfill site to respond to fires occur at the site. Operational activities in addition to an increase in population associated with the operation activity may result in increase demand for emergency services to respond to incidents. Consultation with emergency services suggested that with current operations requiring frequent incident response, there would be capacity for the service to respond to demand created by the new facility if appropriate emergency management planning is undertaken.	**Adverse** **Long term** **National**	**Low**	**Low**	**Negligible (adverse)**
Health and community wellbeing					
Community pride associated with the contribution to the circular economy.	During operation of the project, the recycling center will be used to receive end of life goods together with unwanted but serviceable or repairable products that can be re-used or repurposed. These will then be made available free of charge to other members of the public or third sector organisations for beneficial re-use. Additionally, the Green Waste Processing Facility and Construction and Demolition Waste Processing Facility will receive and process reusable materials for onward resale into the Cayman marketplace. The establishment of the household waste recycling centre, Green Waste Processing Facility and Construction and Demolition Waste Processing Facility may create a sense of civic pride and satisfaction through participation in recycling and contribution to a circular economy.	**Beneficial** **Long term** **National**	**Medium**	**Medium**	**Moderate (beneficial)**
	During operation, the process of diverting solid waste from a conventional landfill to an energy recovery process, would emit considerably less GHG and will offset emissions with every ton of avoided waste to a landfill. Residents of Cayman place a high value on the natural environment and environmental preservation. This is also a key driver of tourism on the Island. A reduction in GHG emissions from the operation of the project may	**Beneficial** **Long term** **National**	**Medium**	**Medium**	**Moderate (beneficial)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. Impact category	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
	create a sense of civic pride and satisfaction through the participation in environmental sustainability efforts.				
Perception of health risk associated with the operation of the project	Residents in the local study area may be concerned that the project may increase the potential for the ingestion of contaminated produce or water or inhaling air-borne pollutants. The perception of potential impacts to health may lead to stress and worry for some community members, which could impact health and wellbeing for some individuals, and may have broader community wellbeing effects.	**Adverse** **Long term** **National**	**Medium**	**Medium**	**Moderate (adverse)**
Changes (actual and perceived) to personal safety and hazard exposure	Energy from waste is an emerging technology in Cayman, although it is a common method of processing waste in a range of countries around the world. Stakeholders indicates that the potential impacts and benefits of energy from waste technology and these types of facilities are not well understood by the community. The perception of negative health impacts from the operation of the project, and uncertainty about the processing technology, may lead to stress and worry for some residents in the area. This could affect overall mental health and wellbeing	**Adverse** **Long term** **National**	**Medium**	**Medium**	**Moderate (adverse)**
Perceived impacts to community safety and community cohesion	The operational workforce (averaging 70 FTE per year) would include a proportion of non-resident workers. In the event that the majority of operational workers are from outside of the regional study area, there is potential that the occurrence of or any perceived anti-social behaviour could be attributed to the presence of operational workers and result in feelings of anxiety and distrust towards project workers by members of the local community. However, given the high proportion of foreign workers currently in Cayman (Section 5.2.3.1), it is anticipated that residents are likely to adapt to an increase to the existing non-residential workforce.	**Adverse** **Long term** **National**	**Low**	**Low**	**Negligible (adverse)**
Changes in perception of personal safety during operation	During operation of the medical waste facility, there may be actual or perceived impacts to community safety as a result of possible theft of contraband drugs destined for incineration. This may concern some residents regarding reduction in safety.	**Adverse** **Long term** **National**	**Low**	**Low**	**Negligible (adverse)**
	The project operation will involve the processing and storing of some combustible materials, particularly in the Construction and Demolition of existing waste facility. This may elevate the fire risk at the project site. Given the current issues associated with fire occurrences at the existing landfill site, residents may be sensitive to safety concerns associated potential fire risk during operation of the project.	**Adverse** **Long term** **National**	**Low**	**Low**	**Negligible (adverse)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. Impact category	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
Environmental quality and natural resources					
Improvements to safety and amenity during operation of the ISWMS	During consultation, the majority of stakeholders noted considerable issues with the existing landfill operations. These concerns include safety impacts associated with persistent fire risk, the unpleasant visual amenity as the existing site is visible from major roads and from tourist destinations, and the odour associated with an open landfill site. The project aims to alleviate the current waste management issues associated with the landfill site by providing an ERF and household waste recycling centre which aims to reduce the amount of physical waste present on the site. The operation of the project will subsequently minimise current amenity and safety impacts being experienced, with stakeholders noting that the project will be beneficial to improve current conditions. Residents in Cayman are likely to be receptive to improvements in current waste management operations which may result in improved amenity.	**Positive** **Long term** **National**	**Medium**	**Medium**	**Moderate (beneficial)**
Noise impacts associated with the operation of the project	During operation of the project, there will be a number of noise and vibration generating activities associated with waste processing and storage. These activities will involve exhaust systems, shredders, grinders, generators and combustion stacks which have the potential to cause an adverse noise impacts at receptors. Sensitive receptors associated with noise impacts are surrounding residential properties, schools, and commercial sites. Some of the activities with highest noise and vibration potential, such as combustion and power generation would occur 24 hours a day, 7 days a week. However, a number of design features have been built into the concept design for the facility to reduce potential noise impacts and ensure compliance with noise criteria at residences. During operation of the ERF, steam purging is a critical hot commissioning activity that occurs once in the lifetime of the plant, and is a high noise generating activity. This process involves a silencer designed to reduce noise from this event and will only occur one time prior to the commencement of operation of the facility. The *Noise Impact Assessment* (GHD, 2023) indicates that the overall noise impact is considered to be low during the daytime and medium moderate during the quiet parts of the evening and night-time. The *Noise Impact Assessment* (GHD, 2023) recommends measures to manage and minimise the potential impacts identified. With appropriate design responses, it is expected that operation of the facility is unlikely to generate significant noise impacts.	**Adverse** **Long term** **National**	**Low**	**Low**	**Negligible (adverse)**
	During operation, the *Noise Impact Assessment* (GHD, 2023) indicated that additional heavy vehicles associated with the transport of waste materials will result in a negligible to minor short-term increase and a	**Adverse** **Long term**	**Low**	**Low**	**Negligible (adverse)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. Impact category	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
	negligible long-term increase to road traffic noise levels at existing sensitive receptors. Residents along haulage routes are likely to be sensitive to operational traffic	**National**			
Changes to air quality due to operation of the project	During operation of the project, there would be increased contaminant concentrations and odour due to the additional emissions. Emissions and odour would be associated with the ERF, incinerators, waste storage and from the transportation of waste. Operation associated with the Green Waste Operations and Construction and Demolition processing may produce dust during processing of materials. Increases in odour and air-borne pollutants may be noticeable in areas around the project site and along haulage routes and could lead some residents and business owners changing their behaviour. This could include spending more time indoors, and closing windows and doors of houses or vehicles. This may impact residents' overall enjoyment of outdoor spaces, and reduce feelings of pride in their local area. However, the *Air Quality Assessment* (GHD, 2023) states that all cumulative impacts are shown to be 'not significant', when mitigation measures are applied.	**Adverse** **Long term** **National**	**Low**	**Low**	**Negligible (adverse)**
Changes to visual amenity and sense of place	During consultation, stakeholders noted that the visual amenity is highly valued by residents and tourists of the Cayman Islands. Additionally, stakeholders noted that the current landfill operations considerably reduce the visual amenity, particularly for surrounding residents, residents in high-rise apartment buildings, tourists using main roads, incoming cruise ships off Seven Mile Beach. The *Seascape and Landscape Visual Considerations Report* (GHD, 2023) found that there may be direct and indirect landscape effects upon the surrounding landscape/townscape/seascape character of areas during operation of the project due to the presence of the ERF and associated resource recovery facilities (for those visual receivers/viewpoints with views to the project site). The operation would be visible from properties close to the project site in surrounding residential settlements and properties in high-rise residential properties on Seven Mile Beach. These properties would currently have views of the existing landfill site. Due to existing amenity impacts associated with the current landfill operation, it is anticipated that residents would be able to adapt to these changes, with stakeholders noting that the project is welcome to provide improvements overall visual amenity.	**Adverse / beneficial** **Long term** **National**	**Low**	**Low**	**Negligible (neutral)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Impact category	Description	Nature/ extent/ context	Magnitude	Sensitivity	Significance rating
Combined amenity impacts	Residents and businesses located adjacent to the project site and along waste haulage routes would potentially experience combined impacts during operation due to noise, dust and visual changes. Residents in the area would be sensitive to these changes, however as the site is located on the existing landfill, it is expected that residents will be able to adapt to these changes. Some residents may be more vulnerable, and there is potential for impacts to overall wellbeing for some.	**Adverse** **Long term** **National**	**Low**	**Low**	**Negligible (adverse)**
Access and connectivity					
Increased traffic during the operation of the project	An increase in light and heavy vehicles on major roads during operation may result in actual or perceived reductions in road safety for road users. However, as noted in the *Traffic Statement* (APEC, 2023), the operation of the project (operating times, waste collection practices, etc.) are expected to be similar to the existing GTLF operations with a marginal increase in staff numbers compared to existing. Trip generation by the ReGen facilities is expected to be in line with the trips currently generated by the GTLF. There are no plans to modify the waste collection practices. During consultation, stakeholders noted that along these roads there are existing traffic issues associated with long travel time during peak hours as well as a high number of traffic accidents. While the operation of the project does not involve any changes to the existing waste collection processes, there may be an increase in private vehicles transporting waste to the resource recovery facilities at the ISWMS, however this is not expected to increase the existing safety issues on the road network.	**Adverse** **Long term** **National**	**Low**	**Low**	**Negligible (adverse)**

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. 8. Mitigation measures

The socio-economic opportunities and impacts identified and assessed in this report would be managed and mitigated and opportunities enhanced through a range of measures recommended in this report, and by other relevant mitigation measures recommended in other EIS specialist studies (such as the noise and vibration assessment, landscape and visual assessment, and traffic and transport assessment) and the *Works Delivery Plan* (ReGen, 2023). Measures for the mitigation and management socio-economic impacts are detailed in Table 8.1.

Table 8.1 Overview of mitigation and enhancement measures

Plan	Description
Employment and skills plan	As detailed in the *Works Delivery Plan* (ReGen,2023), the construction contractor will develop an Employment and skills plan which will be submitted to the Government two months prior to the Works Commencement Date for comment and review. The employment and skills plan would aim to: – Promote the availability of both skilled and unskilled employment opportunities within the project – Encourage the workless and new entrants into the workforce – Ensure compliance with the relevant labour Legislation in the Cayman Islands by setting out the particular requirements – Improve the skills of the local workforce, both new and existing by encouraging transition from expats to local employment over the course of time – Provide apprenticeships, traineeships and work experience opportunities throughout the Works Period The Employment and Skills Plan will include, at a minimum: – Staffing capacity – Staff training and performance assessment procedures – Details of induction training for staff and visitors – Working hours and shift patterns for each Facility – Number of supervisors and use of sub-contractors – Details of experience and qualifications required of key Project personnel – Staff welfare policy – Job descriptions – Backup arrangements in case of shortages, seasonal and exceptional staffing requirements The Contractor will undertake annual reviews of the Employment and Skills Plan to ensure relevance and appropriateness and to monitor performance. As part of the Employment and Skills Plan, the Contractor will develop an “Employees Handbook” that sets out the rights and responsibilities of all members of staff during the Services period.
Consultation framework	As detailed in Chapter 5 of the EIA, a formal consultation framework for the ISWMS has been developed in collaboration with ReGen and the Cayman Islands Government (CIG) to satisfy the public consultation requirements of the EIA as well as engage and educate the public and key stakeholders about the ISWMS Project. The main goals of the consultation framework include: – Satisfy public consultation requirements per the EIA Directive – Improve efficiency of communication with the public and stakeholders – Maintain and improve relationships with stakeholders, including neighbors, and the broader community – Demonstrate willingness to listen and consider input from stakeholders

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Plan	Description
	– Enhance the reputation of ReGen as a responsible entity for managing waste The consultation framework is expected to assist in managing potential concerns about the project once the EIA is on public exhibition, as well as strengthen relationships with key stakeholders (e.g. emergency services, government agencies and residents).
Community Liaison Plan	ReGen has been undertaking engagement with the local community and key stakeholders for the ISWMS prior to this project. There is therefore an established relationship between ReGen, and some local communities and stakeholders. SEIA consultation indicated that ongoing, regular and transparent communication with key stakeholders and residents in Cayman would be important to managing community perceptions of the project in the community. In line with Good Industry Practice, the Contractor will develop and agree with the Government a Community Liaison Plan (CLP), which will cover both the construction and operational phases of the Contract. The CLP will include: – The scope, purpose and timetable for all consultations with relevant stakeholders – Full details of all promotional activities to promote each of the Facilities (including but not limited to the provision of a web site containing community and facility performance information). For the construction period this will be provided through a link to the Contractor's Project website – Measures to proactively encourage community attendance at organised liaison meetings – Details of the general procedures for handling questions, complaints and protests A Community and Stakeholder Engagement Strategy is expected to assist with managing potential concerns about the project, as well as strengthen relationships with key stakeholders (e.g. emergency services, government agencies and residents).
Enquires and complaints plan	A project specific enquiries and complaints plan for the project will be developed to establish the protocol by which standards for dealing with enquiries, complaints, compliments and suggestions from members of the public and other interested parties. The Contractor will allow for enquiries, complaints, compliments and suggestions to be made directly to a member of staff either by telephone, e-mail, via the designated Project website or social media interface or in writing. This will involve a dedicated e-mail address to enable the receipt of complaints, which will facilitate an acknowledgement by return via an automated response. Details of the dedicated web address for enquiries and complaints will be published in newsletters, on site entrance signs, on informational or promotional literature associated with the Project, and on the Contractor's website with an appropriate link. This would be developed and implemented to ensure that residents and stakeholders are notified in a timely manner about construction activities and potential for impacts, accurate information is accessible, and enquiries and complaints are managed in a timely manner.
Procurement plan	As detailed in the *Works Delivery Plan* (ReGen, 2023), the proponent ReGen is committed to supporting the Cayman Islands through the procurement with local businesses. ReGen will develop a procurement plan, to support procurement activities required for the construction and operation of the project, and to leverage local contractors, where feasible. Procurement for the project will, at a minimum, involve: – Bid packages: which will be developed to make best use of local contractors and their capabilities – A procurement plan will be developed to include target dates for scope development Procurement planning will be developed to assist local contractors and businesses in understanding the opportunity and scope of the project procurement requirements and allow for involvement in the tendering process for bid packages.

This document is in draft form. The contents, including any opinions, conclusions or recommendations contained in, or which may be implied from, this draft document must not be relied upon. GHD reserves the right, at any time, without notice, to modify or retract any part or all of the draft document. To the maximum extent permitted by law, GHD disclaims any responsibility or liability arising from or in connection with this draft document.

Table 8.2 summarises the mitigation and enhancement measures applicable to the socio-economic impact identified in Sections 6 and 7 of this report, and from other EIA specialist studies.

Table 8.2 Summary of mitigation and enhancement measures for socio-economic impacts

Impact category	Mitigation or enhancement	Relevant EIA specialist study
Population and demographic change from construction workforce	Employment and skills plan	SEIA
Increase in direct local employment during construction.	Employment and skills plan	SEIA
Increased training opportunities	Employment and skills plan	SEIA
Increased competition for workers in local and regional labour market	Employment and skills plan	SEIA
Procurement opportunities for local businesses and the purchase of goods and services during construction	Procurement plan	SEIA
Indirect employment through procurement opportunities	Procurement plan	SEIA
Increased in local trade associated with expenditure of wages	Procurement plan	SEIA
Increased demand for housing and accommodation access	Employment and skills plan Consultation framework Community Liaison Plan	SEIA
Increased demand for community facilities and services.	Consultation framework Community Liaison Plan	SEIA
Increased demand on emergency services	Consultation framework Community Liaison Plan	SEIA
Perceived impacts to community safety and community cohesion	Consultation framework Community Liaison Plan Enquires and complaints plan	SEIA
Changes in perception of personal safety	Consultation framework Community Liaison Plan Enquires and complaints plan	SEIA
Mental health of non-resident workers	Employment and skills plan	SEIA
Increased noise, vibration and dust levels due to construction activities	Environmental Management Plan Mitigation measures will be incorporated into the site design to reduce noise emissions where feasible and Best Available Technology (BAT) will be adopted, which will further reduce noise from the ISWMS at receptors Consultation framework Community Liaison Plan Enquires and complaints plan	Noise and Vibration Impact Assessment Air Quality Impact Assessment
Changes to visual amenity and sense of place	Consultation framework Community Liaison Plan Enquires and complaints plan	Landscape and Visual Assessment

9. Conclusion

This SEIA has identified and addressed the key socio-economic impacts associated with the project and provides a set of recommended mitigation measures.

The key positive socio-economic impacts with the potential to occur during construction are primarily related to an increase in employment opportunities for Cayman residents, procurement opportunities for businesses to supply goods and services, and minor increase in revenue for local businesses due to construction workers purchasing meals and other services.

The potential negative socio-economic impacts that may occur during construction are summarised below:

– Reduced amenity for some residents, businesses and community facilities in close proximity to construction activities.
– Disruptions to traffic conditions, resulting in delays and potential for increased travel times for people travelling in the local and regional area, including local community members and regional road users.

The key socio-economic benefits of the project are primarily related to the regional economic benefits associated with the development of a new, technologically advanced, industry and the diversification of the economy. In particular, the project has the potential for capacity building and upskilling of the existing workforce, and provide opportunities for new business generation to support its operations in Cayman as ERF technology is a new industry for the region.

Additionally, due to the nature of the facility, involving the production of green energy, the recovery and reusing of materials and the overall improvements to current waste management practices in Cayman, residents may experience a sense of community pride associated with the contribution to the circular economy. This may in turn support the tourism industry to achieve its aspirations for sustainable and nature-based tourism practices as a large waste contributor on the island.

The key negative socio-economic impacts during operation are related to the perception health and safety risk associated with the operation of the project and potential changes to local amenity for some residents and businesses in close proximity to the project site due to changes in air quality, noise and visual amenity.

The positive and negative social impacts identified and assessed in this report would be managed and mitigated through a range of measures, including those recommended in other EIS technical papers.

The SEIA has identified the following recommended mitigation measures from the *Works Delivery Plan* (ReGen, 2023) to minimise potential social impacts, and to enhance social benefits:

– Employment and skills plan
– Consultation framework
– Community Liaison Plan
– Enquires and complaints plan
– Procurement plan
